[1] Glass-Blowing. A Laboratory Handbook. By Bernard D. Bolas. With numerous diagrams in the text by Naomi Bolas. London: George Routledge and Sons, Ltd.; New York: E. P. Dutton and Co. 1921. Pp. 106. 3s. 6d.

no difference was made between a girl who fell for the first time through the dastardly act of a designing man and a girl who had already adopted the life of a prostitute, and who probably herself deceived. Prostitution led to other forms of crime, and it was easy for a girl to make money by blackmail.

Captain LOSEBY seconded the motion for rejection, on the ground that certain clauses of the measure struck at the root of the principle upon which the criminal law of the country was based.

Mr. SHORTT (Home Secretary) supported the Bill, and pointed out that every single provision of it had been approved by a Joint Committee of the House of Lords and the House of Commons. It did not seek to make people moral by legislation, but to prevent them carrying out immoral purposes just at their own will.

After further discussion the Bill was read a second time without a division.

MONDAY, JULY 18TH.

Anthrax-infected Brushes.

Major KELLEY asked the President of the Board of Trade whether, in consultation with the Ministry of Health, he had safeguarded the country against the importation of anthrax-infected brushes.—Sir A. MOND (Minister of Health) replied: Samples of imported brushes from various sources have been examined from time to time, but so far only shaving brushes of Japanese origin have been definitely found to be anthrax-infected and capable of conveying infection to human beings. The further importation of Japanese shaving brushes into this country was prohibited in February, 1920, by an Order in Council which is still in force.

The Heat Wave and Rabies.

Major KELLEY asked the Minister of Agriculture whether, in view of the exceptionally hot summer, the public had any reason to apprehend a spread of rabies in dogs.—Sir A. GRIFFITH-BOSCAWEN replied: I am advised that inasmuch as rabies is a contagious disease which is only transmitted by means of the bite of an infected dog there is no reason to apprehend an increase in the number of cases of rabies on account of the hot weather.

Vaccination and Small-pox.

Mr. ROBERT YOUNG asked the Secretary for Scotland whether any of the cases classified as unvaccinated of those occurring in the Glasgow outbreak of small-pox in 1920 had been vaccinated at any time in their lives: and if so, what were the ages of such cases, and what was the interval between vaccination and the development of small-pox.—Mr. MUNRO replied: No case in the list of unvaccinated persons had been vaccinated *before* exposure to infection. Of the 128 cases classified as unvaccinated, 19, who were contacts with previous cases, were vaccinated during the outbreak, but *after* exposure to infection. The ages of the 19 cases were:—

Under 5	8 cases.	10–15	4 cases.
5–10	6 ,,	Over 15	1 case.

The intervals between date of vaccination and commencement of attack were:—

Days	4	5	6	7	8	9	10	11
Cases	1	3	3	2	5	2	1	2

Mr. YOUNG also asked the Secretary for Scotland whether the medical officer for Glasgow would be requested to inquire into those cases of small-pox classified by him in 1920 as unvaccinated, as he did in the small-pox outbreak in Glasgow in 1903–4, when he discovered that a number of the alleged unvaccinated cases had been vaccinated in infancy.—Mr. MUNRO replied: The answer is in the negative. The inquiry suggested would not affect the validity of the statistics, nor afford any information commensurate with the trouble and expense involved to the local authority.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, July 25th.—2 P.M., Mr. D. Armour: Operations.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations and Visit to Wards. 2.30 P.M., Mr. Addison: Visit to Surgical Wards.

WEDNESDAY.—2 P.M., Mr. D. Armour: Visit to Surgical Wards. Mr. Addison: Operations.

THURSDAY.—2.30 P.M., Dr. A. Saunders: Visit to Medical Wards.

FRIDAY.—2.30 P.M., Dr. Pritchard: Visit to Medical Wards. Mr. Baldwin: Operations.

Daily:—10 A.M., Visit of Post-Graduates to Wards. 2 P.M., In-patient Clinics and Operations.

Appointments.

PEARSON, W. J., D.M. Oxon., has been appointed Physician-in-Charge of the Children's Department at Charing Cross Hospital.

Certifying Surgeons under the Factory and Workshop Acts: ROBERTS, J. C. L., M.D. Camb. (Ruabon); EVANS, J. (West Drayton).

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne District Infirmary.—H.S. £200.

Ayr County Hospital.—Lady Supt.

Bedford County Hospital.—H.S. £200. Asst. H.S. £150.

Bethlem Hospital.—Res. H.P. £25 per quarter.

Birmingham General Hospital.—Two H.P's. £100. H.S's. to Special Depts. £125. H.S. £100.

Birmingham, Queen's Hospital.—Surg. Registrar. £100.

Bootle Borough Hospital, Derby-road.—Junior H.S. £150.

Bradford Royal Infirmary.—H.S. £200.

Brighton, Royal Sussex County Hospital.—Casualty H.S. £120.

Bristol, Cossham Memorial Hospital, Kingswood.—Res. M.O. £200.

Bristol Royal Infirmary.—Cas. and Ophth. H.S.'s £120.

British Honduras.—Asst. M.O. $2430.

Cardiff, King Edward VII. Hospital.—Cas. H.S. £200.

Carlisle Non-Provident Dispensary.—Res. M.O. £300.

Doncaster Royal Infirmary and Dispensary.—Sen. H.S. £225. Jun. H.S. £200.

Downpatrick, Down District Asylum.—Sen. and Jun. Asst. M.O's. £350 and £300 respectively.

Evelina Hospital, Southwark, S.E.—H.P. H.S. Each £160.

Glasgow, Bellahouston Hospital.—Visiting M.O. to Ear, Nose and Throat Dept. £450.

Gloucester County Asylum.—Jun. Asst. M.O. £350.

Great Yarmouth Hospital.—H.S. £200.

Jersey Poor House Infirmary.—M.O. £750.

Lancashire County Asylum, Winwick, Warrington.—Second Asst. M.O. £300.

Leeds Public Dispensary.—Sen. Res. M.O. £250.

Leith Hospital.—Res. P. Res. M.O. Each 50 guineas.

Manchester, Ancoats Hospital.—H.S. £150.

Manchester University.—Demonstrator of Pathology. £350.

Manchester, Victoria Memorial Jewish Hospital, Cheetham.—Res. M.O. £150.

Middleton-in-Wharfedale Sanatorium.—Asst. M.O. £500.

Newcastle-upon-Tyne Hospital for Diseases of the Skin.—Hon. Clin. Asst.

Newport (Mon.), Royal Gwent Hospital.—H.S. £200.

Northamptonshire County Council.—Asst. Tuberculosis Officer. £500.

Nottingham General Hospital.—Res. Cas. O. £250.

Plymouth, South Devon and East Cornwall Hospital.—H.P. £150.

Reading, Royal Berkshire Hospital.—H.P. Second H.S. Each £200.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Royal Naval Medical Service.—Surg.-Lieuts. 26*s.* 6*d.* per diem.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. £100.

St. George's Hospital, S.W.—Res. H.S. £50.

Salford Royal Hospital.—H.S. Cas. H.S. Each £150.

Salisbury General Infirmary.—Asst. H.S. £150.

Seamen's Hospital Society, Greenwich, S.E.—H.P. H.S. Each £150.

Torquay, Torbay Hospital.—H.S. £200.

Union of South Africa (Natal Provincial Administration).—House Surgeons, Grey's Hospital, Pietermaritzburg. £400.

West London Hospital, Hammersmith-road, W.—H.P. £100.

Wigan County Borough.—Tuberculosis Officer and Asst. M.O.H. £550.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £200.

Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £350.

Births, Marriages, and Deaths.

BIRTHS.

GRAY.—On July 12th, at Oporto, Portugal, the wife of St. George B. D. Gray, M.B., B.S., M.R.C.S., L.R.C.P., of a daughter.

HOLMES.—On July 11th, at Eldon House, Harrogate, the wife of Geoffrey Holmes, M.B., B.Ch. Cantab, of a son.

MOORE.—On July 12th, at St. Paul's-road, Clifton, Bristol, the wife of Clifford A. Moore, M.S., F.R.C.S., of a son.

MARRIAGES.

ALEXANDER—JACKSON.—On July 14th, at Ballycastle, co. Antrim, John Alexander, M.B., Sefton Park, Liverpool, to Florence, daughter of the Rev. J. Jackson, D.D., Ballycastle.

DEATHS.

EVANS.—On July 15th, at Bournemouth, Lieut.-Colonel J. W. Evans, I.M.S., of Trevaughan, Carmarthen, after a long illness.

MORRIS.—On July 17th, at Belmont-road, Wallington, Surrey, Graham Morris, M.D. Brux., M.R.C.S., L.R.C.P. Lond., Hon. Capt. R.A.M.C., aged 60.

with all the other mechanisms which take part in the general bodily reaction to nocuous stimuli, the galvanic reaction is conditioned by the response of the thalamic system. That changes in the peripheral blood-supply have nothing to do with the response was shown by the experiment of Veraguth, who obtained normal responses from a limb exsanguinated by an Esmarch bandage.

I now propose to deal with some of the aspects of the galvanic reflex that will prove of service in the objective study of the bodily response to cerebral activity. Before doing so, I will indicate briefly the technique that can be usefully employed for this purpose. In my own experiments I have been in the habit of measuring the bodily resistance to a current of a couple of Leclanché cells which is passed through the body from two liquid electrodes of normal saline into which zinc terminals dip. The subject is seated with the hands immersed one in either electrode, and forms the fourth arm of the familiar Wheatstone bridge circuit. I prefer the liquid electrodes to the solid zinc electrodes strapped on to the back and front of a single hand, because slight shifting of the electrodes due to movements occurs rather easily when the latter procedure is adopted; further, the low resistance measured allows its easy demonstration to the uninitiated without having to multiply up the results by using unequal ratio arms in the resistance box. The point is, of course, of no importance. For experimental work I have abandoned the moving coil galvanometer for the Einthoven instrument, since with this type of galvanometer it is alone possible to measure time relations with any degree of accuracy, and an additional interest is given to the records by the appearance of the heart beats in the curves. Further, with the double-string instrument which I owe to the generosity of Mr. Alfred Teniers it is possible to obtain either simultaneous records of the galvanic response of two parts of the body or of muscular or respiratory variations accompanying the galvanic reflex.

NATURE OF STIMULUS EVOKING GALVANIC RESPONSE.

The first subject for inquiry is as to the nature of the stimulus that evokes the galvanic response. Practically all those who have concerned themselves with this reflex agree that stimuli adequate for the galvanic reflex are capable of causing an affective state. We are in no way entitled to draw the inference that the occurrence of an affective state is necessary to the exhibition of the reflex, and still less that the occurrence of the reflex conditions an affective state. While the examination of the relation between bodily activity and states of feeling may be reserved at this stage for later discussion, it must here be pointed out that an affective state, to exist at all, must be experienced by the subject. Now, a galvanic response may occur without the subjective experience of an affective state. I have frequently observed a response to be elicited by a stimulus when the subject affirms that the stimulus has for him no feeling tone. This may be best observed in the performance of word association experiments. The response to a certain word may be marked and yet when the subject is interrogated he is at first unable to discover any association of emotional significance in the word, and, moreover, he assures me that the word left him absolutely indifferent. It is true that further examination generally succeeds in recalling a hidden emotional significance, and thus reveals that the stimulus activated a specific reflex system that at one time had a nexus with the mechanism of feeling; but that is not the point. If we accept the assurance of the subject, we must believe that the reflex occurred without his experiencing any feeling connected with the word. To talk of a subconscious feeling is, of course, to talk nonsense. The same point may be verified by purely introspective investigation. When a painful or presumably painful stimulus is applied to the hand, such as touching it for a moment with a flaming match, a well-marked reaction will be obtained.

If, however, the experiment be repeated a number of times in succession without the injury inflicted corresponding to that which was anticipated at the first stimulation, the subject becomes indifferent and possibly bored with the performance, and yet with each application of the stimulus there is still a galvanic reaction though the subject is well assured that he feels no apprehension. To appreciate the cogency of the experiment one must oneself serve as a subject, and there is no mistaking the genuine surprise with which one observes a reaction to a stimulus that has become a matter of indifference. I shall refer to this experiment again when we come to discuss conditioned reflexes. Here its importance lies in the fact that the reaction takes place in the absence of an affective state. Many observers have maintained that the galvanic reflex accompanies mental effort as well as states of feeling. We have just now discussed the sensory concomitants of effort and I hope to have succeeded in demonstrating that they constitute what we know as an affective state; but I do not consider that they are normally accompanied by a galvanic reaction. When, however, an intense effort results in one or other of its sensory factors assuming overwhelming proportions, we have said that it is presented as a distinct disagreeable sensation and may as such arouse the same system of reflexes as it would were it a sensation caused by a specific stimulus. In this connexion I instanced the feeling of suffocation during a cell count. In the performance of word association tests I have generally found that the first three or four word reactions in the examination of a a new and nervous subject are accompanied by a galvanometric deflection, even though they be essentially neutral words. This is simply an expression of the state of anxiety on the part of the subject, who soon settles down and responds electrically only to words having an emotional significance.

PARTIAL CLEARING UP OF CONFUSION BETWEEN SUBJECTIVE AND OBJECTIVE STANDARDS.

These considerations indicate some of the difficulties to be encountered in any attempt to elucidate the meaning of a physical response by an appeal to subjective evidence; a similar confusion of subjective with objective standards has proved to be such a stumbling-block in the physiology of the afferent nervous system. In that case the problem for the physiologist is not what is the presentation to consciousness following on the stimulation of an afferent nerve-ending, but what are the reflexes that such stimulation evokes, and by what form of stimulus is the receptor organ excited. Thanks to the introduction of the idea of the existence of a system for the transmission of nocuous stimuli by Sherrington, and its correlation with the thalamic reflex system by Head and Holmes, the physiology of the nociceptoral nervous system has been made relatively clear, and we have eliminated many of the obscurities that were so perplexing when the subjective sensations of the patient were our only guide. Likewise, in considering the galvanic reflex the first question to be considered is what are the objective characteristics of the stimuli that evoke this increase of conductivity on the part of the skin—an increase which we have reason to consider to be an index of a general increase of functional activity and to be correlated to certain states of feeling. The answer is that in the first place any type of stimulus that tends to cause damage to the body, or that threatens such a change in the environment as is likely to result in bodily damage, will prove to be an adequate stimulus. In the second place we must recognise not only actual bodily damage but the disturbance of the smooth working of bodily activities as the characteristic of another class of stimuli which will evoke the generalised bodily reaction of which the galvanic reflex is a sign. The first class of these stimuli is represented by such physical disturbances as may result from a blow, a burn, a prick or pinch; or those acting from a distance, such as loud sounds, blinding lights, or noxious smells; or, again, endogenous stimuli, such as colic or neuralgia.

have been found during the stage at which greater demands were being made on the heart. That is to say, the greater the work done by the heart the greater the chemical changes necessary to supply energy. A motor-car may be running steadily with an even beat of its engines along a level road. When it comes to a hill it will slow up and finally stop unless the chauffeur increases the chemical changes and the energy of each explosion within the cylinder by opening the throttle and letting in more mixture of petrol and air. In the case of the heart there is no chauffeur, but there is some automatic regulation by which the heart increases its chemical changes and therefore the energy of each beat in exact proportion to the work which is demanded of it. It is the nature of this automatic regulation which concerns us now.

The Nature of the Automatic Regulation of the Heart.

By a careful observation of the changes in the heart in the experiment described above we may arrive at some clue to the nature of the pressure, but more accurate methods are necessary if we are to be certain of the correctness of our guess. We must under these varying conditions measure: (1) the pressure in the heart cavities produced at each contraction; (2) the volume of the heart cavities—i.e., the length of the muscle fibres of their walls. The first we measured in the experiment described by connecting the interior of each cavity in turn with a quickly acting manometer, the excursions of which are registered by an optical method so as to avoid the instrumental vibrations of a lever. The curve of pressure obtained under two conditions—i.e., low and high artificial resistance—could then be plotted. It must be remembered that the heart was sending on in each case all the blood that it received, though the work necessary under the high pressure was two or three times as great as that necessary to send on the blood at the low pressure. To measure the volume of the heart the ventricles are enclosed in an instrument known as a cardiometer. This communicates with a piston recorder so that the change of the volume of the ventricles at each beat can be registered on a moving surface.

The question we have to decide is, how does the heart know when it is relaxed that at the next contraction it will have to exert more force than it did previously, when the arterial resistance to be overcome was lower? If we measure the pressure in the ventricles in the manner just described we find that during the period of relaxation of the ventricles the pressure in its cavities is approximately zero, whether the artificial pressure which it has to overcome at its next beat is 50 or 150 mm. Hg. It is not, therefore, the tension on the walls of the heart which determines the strength of its contraction at its next beat. When, however, we come to measure the volume of the heart, we find that in the isolated heart this is directly proportioned to the work which the heart has to accomplish. Thus we find that the larger the heart—i.e., the more it is dilated during diastole, the greater is the pressure that it will get up at the succeeding contraction or systole.

We may put this in another form, as is shown by continuing our experiment over several hours, when we find that the worse the condition of the heart muscle, the more it must dilate in order to get up an adequate pressure. Other things remaining equal we thus see that the volume of the heart during diastole is a measure of its physiological condition, and we are not surprised that a failing heart means a dilated heart. Of course, there is a limit to this power of adaptation. As the heart dilates it is working at an ever-increasing mechanical disadvantage, and a point will finally arise at which this disadvantage more than counterbalances the physiological effect of dilatation. The heart then dilates widely and fails to empty its contents. Dilatation of the heart means elongation of the muscular fibres composing its walls, so that we may put the law of the heart in another way and say that the longer its muscle fibres the greater is the energy developed at each contraction. But in this form this wonderful power of adaptation possessed by the heart becomes part of the general properties of all muscular tissues, since the same rule applies to the fibres composing our voluntary muscles. Can we obtain any more precise and physiological conception of what is involved in this relationship between length of fibre and strength of contraction? Microscopic examination of the fibres, either of the heart or of voluntary muscles, show that these are composed of innumerable fibrils, so that internally the muscle fibre is made up of structures presenting an enormous extension of longitudinal surfaces. The more the muscle is stretched the greater will be the extent of these surfaces. A large amount of evidence, based on the electrical and chemical changes occurring in muscle as a result of excitation, points to the contraction as being essentially a surface phenomenon—a molecular change over the whole of the longitudinal surface which may result in a polarisation or depolarisation of its service and an increase of its surface tension, so that the muscle is a surface tension machine in which there is on excitation a direct conversion of chemical into surface energy. The greater the surface the greater will be the number of molecules involved, so that increased length of muscle must increase at the same time the total chemical changes and the total tension produced by the summation of the surface tension of each fibril.

It is only by such a change of molecular dimensions that we can explain the rapidity of events in a muscle (the insect wing muscle can contract and relax 300 times per second), or the high efficiency of the machine, an efficiency which A. V. Hill has shown may amount to 100 per cent. for each isolated contraction and over a length of time to 50 per cent. As directly measured in the heart-lung preparation we find a mechanical efficiency of about 30 per cent.

Conclusion.

It is impossible here to enter into the application of this law of the heart, but so far it has not failed in accounting for the behaviour of this organ under all manner of conditions either in health or disease. It is important to remember, however, that we are dealing here with the isolated heart. In the natural body the mechanisms which we have studied are fenced round, protected and aided by the complex activity of the central nervous system, which is always acting on the heart, balancing its activity against that of the blood-vessels, and coördinating it with the events which are occurring in every other part of the body. All these factors must be taken into account when we are endeavouring to form a conception of the total behaviour of this organ under the varying activities of the intact animal.

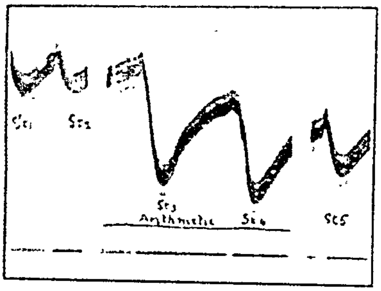
EARLY BOOKS ON MEDICINE AND ANATOMY.

ON the afternoon of to-day, Friday, July 22nd, Messrs. Hodgson, at their premises in Chancery-lane, are disposing of an important collection of early books on anatomy and medical science formed by Prof. John Cleland, M.D., F.R.S., Emeritus Professor of Anatomy in Glasgow University. There are three incunabula (books printed before 1500 A.D.), and well over 100 other early books. Berengarius Carpus, the first to describe the vermiform appendix; Highmore, with his own account of the "antrum"; Thomas Vicary; Harvey; Spigelius; G. Asellius, discoverer of the "lacteal veins"; Bartholinus (four separate volumes); Meibomius; Eustachius; Stenson; Valsalva; Morgagni; Cowper; Malpighi; Boerhaave; Vesalius; Falloppius (sic); Willis; Cheselden—these are but a selection of the eponymous sixteenth and seventeenth century worthies whose original works are catalogued in this sale. The oldest book of the whole collection is the Natural Theology of Raimond de Sebondi printed at Daventry in 1480, and dignified by the mystic parentheses [H.C. 14067], which mean that the two great authorities on fifteenth century printing, Hain and Copinger, have collated, described, and numbered it. The other two, both of 1481, are mentioned by Hain alone, apparently; one is a translation of Galen, published at Ulm, and the second Articella's encyclopædia of ancient text-books of medicine, published with a commentary at Venice.

RATS AND THE FILM.

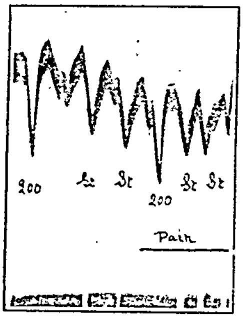
ON July 15th an important weapon was released for use against the rat, in the shape of an excellent two-reel film prepared for the Incorporated Vermin Repression Society, by the Industrial Film Association, and exhibited to members of the Society and press representatives at the premises of the American Company in Wardour-street, London, W. The film occupied nearly half an hour, the first reel setting forth the ravages of the rat, and the second the means of prevention. A solitary rat was first thrown on the screen like any other kinema villain; there followed quayside glimpses with vessels at anchor, and rats skipping across lowered gangways and sliding down unguarded mooring-cables to disappear ashore. The scene shifted inland; a poultry-enclosure appeared, and was subjected to a grisly raid. Another scene was set in a larder; rats climbed the shelves and fouled the food, which later was borne away by an unobservant maid and deposited on the dinner-table with dramatic results. But all was not lost; in the gloom of his laboratory a scientist held a test-tube to the light; *Trichina spiralis* sprawled enormous across the screen, and then gave place to welcome methods of rat destruction. A harassed shopkeeper laid a large spring trap by his plundered goods, and we were privileged to see justice done on a raider. Varnish and open-air wire and "run" traps were shown in use, and the film concluded with a comparison of rat repression 20 years ago and to-day. The system of the old-style rat-catcher seemed to consist of drinking deeply from a pint mug; contrasted with his method was that of the Vermin Repression Society's experts shown at work in a warehouse. Guns, nets, ferrets, and stimulus. The work performed, be it noted, was not responsible for any diminution of resistance per se. I have, however, constantly obtained this modification of the reaction to moderate stimuli, slight though it be, so long as the work on which the subject is engaged does not prove unduly irksome. When the resentment or the discomfort of strenuous work reaches such a pitch as in itself to produce a bodily reaction in the shape of a diminution of resistance, the response to the initial stimulus is diminished, just as we see occurred in this record when the subject was undergoing painful stimulation. When, however, the stimulus is a maximal one, such as is produced by the firing of a pistol close behind the subject, it ceases to be possible to modify the response either by work or by any moderate degree of pain. Fig. 5 is the record of what is apparently a fatigue effect in the galvanic response to a series of uniform auditory stimuli. This apparent fatigue cannot be attributed to exhaustion of the effector mechanism of the response, that is either to the skin, the centrifugal nerves going thereto, or the nerve cells governing them, for if an adequate stimulus of a different nature to that of the series be administered at the beginning and at the end of the series it will be found to evoke approximately the same degree of response. Under the conditions of the experiment, which consists in the production of a short series of sounds of equal and moderate intensity, the effect cannot be due to fatigue either of the peripheral receptor mechanism or of the cortical receptor centres. We may therefore ascribe the progressive diminution of the response to some change occurring in the nervous mechanism connecting the receptor system with the effector system of the galvanic reflex. The term "progressive indifference" probably describes this change better than fatigue; for if in the middle of the series of moderate stimuli we intercalate one of greater magnitude we obtain a response approximately equal to that aroused by a stimulus of the same magnitude administered before the beginning of the series. It is noteworthy that after the intercalation of the powerful stimulus the descending series of responses is interrupted for the next two stimuli which show some degree of augmentation.

FIG. 3.



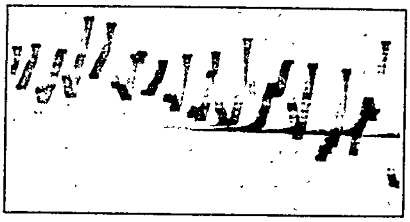
Reaction to uniform stimuli (prick). 1 and 2 before, 3 and 4 during, and 5 after mental arithmetic.

FIG. 4.



Reaction to uniform stimuli (prick) before and during painful faradisation. Graduation of 200 ohms.

FIG. 5.



Fatigue effect of galvanic reflex to uniform series of sound stimuli.

VARIATION OF RESPONSE WITH STIMULUS.

When the patient is subjected to a brief examination not lasting over ten minutes or so the magnitude of the response can be shown to vary directly with the strength of the stimulus. Fig. 6 shows the response to a series of break induction shots of increasing strength. This relation between the strength of the stimulus and the response is obviously a fact of some importance, but we must hesitate before we pronounce on the relative efficiency of any two verbal stimuli or stimuli evoked by the subject's own representations on the strength of an examination of the galvanic responses elicited. Even with simple and easily controlled physical stimuli two such stimulations of different strengths can only be counted upon to give proportionate responses when they are not separated at too great an interval and the general attitude and condition of the subject is approximately the same. After an initial intense stimulus with its concomitant response the resistance does not immediately rise to the old level, and so long as the slight general diminution in resistance continues the response to subsequent stimuli, of whatever their nature, will be somewhat greater than formerly. In the study of the galvanic reactions of neurotics undergoing a prolonged examination this tendency must not be overlooked. If a painful stimulus be repeatedly administered, and its administration be accompanied by some sound or movement on the part of the observer, after a time the repetition of this sound or movement will be in itself sufficient to produce a response equal to that caused by the stimulus. We shall, in fact, have established what Bechterew calls a conditioned reflex. Fig. 7 shows such a conditioned reflex. A painful stimulus was administered to a subject who was instructed to press a key which completed the circuit of an electric signal every time that he felt the stimulus. In addition to the motor reaction the galvanic reaction to the stimulus, was recorded. Every time that the painful stimulus which was an induction shock, was administered, the subject who sat with his eyes closed heard the click of the key that opened the circuit for the break induction shock. After the reaction had been repeated a sufficient number of times the key was clicked as usual, but the current was prevented from reaching the subject by a previous disconnexion of the circuit. On hearing the accustomed click the subject reacted in the accustomed fashion both by the signal and by a galvanic response, which will be seen to have been of no less magnitude than that responding to the last two occasions of the series when the induction shock was really administered. We shall see in the next lecture what light a consideration of these conditioned reflexes throws on the relation between the bodily response and the affective state.

PROBLEM OF SKIN RESISTANCE.

The relation of the initial resistance of the skin to the magnitude of the galvanic response is a very difficult point to determine. Waller has shown that the skin resistance undergoes a diurnal variation following closely the diurnal variation of temperature. I took advantage of this observation to determine the relation of the galvanic responses evoked by uniform stimuli to the initial skin resistance. Maximal stimuli were used, and for this purpose I found a pistol shot most convenient. A rough correspondence between the resistance of the skin and the galvanic reflex throughout the day is shown by Fig. 8. This chart represents the mean of observations conducted on three successive days, but the difficulties in obtaining the subject at any one time under approximately the same conditions are very great. For what it is worth, it seems to indicate clearly that the maximum response occurs round about mid-day when the

Croonian Lectures

ON

THE OBJECTIVE STUDY OF NEUROSIS.

Delivered on June 14th before the Royal College of Physicians of London,

BY F. L. GOLLA, M.B. OXON., F.R.C.P. LOND.,
PHYSICIAN TO ST. GEORGE'S HOSPITAL.

LECTURE II.[1]

In the preceding lecture we reviewed some of the objective aspects of effort. Before proceeding to study the other bodily concomitants of cerebral activity, I wish to summarise what objective study has taught us of the state of activity that we designate as effort. In the first place, all the phenomena recorded were in the nature of increased bodily activity and not of the inhibition of activity, that it might be thought would permit the more readily the uninterrupted response of the specific mechanism to the stimulus. We found that the generalised bodily reaction of effort bore a direct relation to the difficulty—that is, to the chance of failure of the specific mechanism in performing its appropriate action and we noted that when this bodily response experienced any diminution, the accuracy of the specific performance was likewise diminished. Lastly, we found that the net result of such of the bodily changes observed in effort was to increase the general efficiency of the body, whether by accelerating and increasing the simpler motor reflexes or by influencing the blood-supply of the nervous system by an increase of the intrathoracic pressure and vasomotor changes.

Now let us interrogate our consciousness as to the feeling that we experience during effort. As in the case of other affective states that we shall study later, we find that to attend to a feeling is, to a great extent, to lose it. We are aware of certain respiratory sensations, a certain sense of increased cardiac action, of intracranial pressure, and of postural tension. Sometimes one, sometimes another of the constituents of this feeling of effort becomes so dominant that the vague feeling is swamped by a distinct sensation such as I instanced in the case of the respiratory symptoms experienced in performing a count of the particles ingested by phagocytes. The general sum-total of the sensory presentation of the bodily changes of effort is a disagreeable one. The sooner that we can cease from effort and find our specific task performed the better pleased we are.

Ribot has emphasised the fact that nobody really has pleasure in work itself, it is to its accomplishment that we really look forward with pleasure. Now whether we regard effort from a purely mechanical point of view, or whether we take cognisance of its affective aspect, the conclusions that will be drawn are much the same. A stimulus is presented, the specific response to which is inadequate, or else the task would be accomplished with mathematical certainty. When such a stimulus fails to arouse an adequate response on account of its own feeble nature, nothing further happens except that the response will itself be a feeble one. When, however, the stimulus is powerful and insistent and the mechanism of response is inadequate another and more diffuse constellation of reflexes is aroused. Various bodily activities are brought into action, all of which tend to increase the efficiency of the specific mechanism. The sensory presentation of these bodily activities is a disagreeable feeling which we do our best to allay by accomplishing the specific action demanded. Viewed from this angle we shall see that the mechanism of effort resembles that of the affective states that we are about to consider, and further, that no distinction can be drawn between effort and the conception of attention as propounded by Locke and in a less incisive fashion by Hamilton. It will be obvious that when through either innate or acquired disability the specific mechanisms are everywhere inadequate to respond to the tasks that they are called upon to perform, the never-ceasing activity of the mechanism of effort will prove exhausting to the body, and in its sensory aspects a most distressing form of neurotic disturbance.

REACTION MANIFESTED BY CHANGE IN ELECTRICAL PROPERTIES OF THE SKIN.

Hitherto the reactions that we have studied have been occasioned by the activity of striated or non-striated muscular tissue. I now propose to deal with a reaction that is manifested by change in the electrical properties of the skin. This reaction was first described by Féré in 1888 as an emotional response, manifesting itself by a diminution of the resistance of the body to the passage of an electric current. Galvanometric deflections occurring when the skin was explored by a pair of electrodes were independently described by Tarchanow in 1890, and found by him to occur as responses to physical and psychical stimulation. He considered them to be due to secretory currents of the skin glands.

The investigations of both of these observers were to a great extent ignored, and the same fate befell Stricker's confirmation of Tarchanow's experiments in 1902. It was not till 1904 that the subject was reinvestigated, when Veraguth, stimulated by some preliminary observations on bodily resistance by E. K. Müller, confirmed the observations of Féré and gave the first systematic exposition of what he termed the "physico-psycho-galvanic reflex." He described this reflex as a diminution of the resistance of the skin to the passage of a constant current occurring as a response to stimuli which caused an alteration of the affective state. It is not possible in the course of these lectures to deal with the mass of observations that have since accumulated from the work of the many experimenters who, subsequently to Féré and Veraguth, have investigated this phenomenon. Nor are we concerned for the moment with the physical nature of the response. It is sufficient to state that the galvanometric effect is beyond all doubt due to a diminution of the electrical resistance offered to the passage of a constant current by the skin, and that this diminution is exhibited as a maximum effect in the palms of the hands, a little less obviously in the sole of the foot, and scarcely at all in other parts of the skin. This statement, which is founded on the careful exploration of all parts of the body surfac by Gildermeister, has been confirmed by every observer who has worked on the subject.

The work of Crile and his pupils has shown that a increase of electrical conductivity, or conversely a diminution of resistance, is associated in all tissues, with an increase of their metabolic activity; we may tentatively regard the galvanic response as a sign of the increased activity of the gland-bearing area of the skin. If it be to the activity of the cutaneous glands themselves that we must ascribe the galvanic reflex it is certainly not due to the gross manifestations of that activity by the excretion of sweat. In 1918 I had a neurotic patient who suffered from hyperidrosis of both hands, the sweat falling off from the tips of the fingers in drops. I found that this patient exhibited the galvanic response to all adequate stimuli in a marked degree, although the palms were covered by a thin layer of sweat, and it was unthinkable that any actual increase in the amount of fluid excreted should have an influence on the conductivity of the sodden skin. I showed the case to Prof. Waller, and he also remarked on the magnitude of the galvanic response given by this patient. It is further obvious that the galvanic response, if it be associated with glandular activity, can only be governed by the centrifugal nerve impulses that travel through the fibres of the sympathetic, and we shall later see reason to believe that, in common manifested by a forward movement of the head. A painful stimulus is responded to by a retraction of the head. This might appear to be an example of a purposive movement, the subject endeavouring to withdraw from the vicinity of the painful stimulus, but on applying the stimulus to the back instead of in front the same retraction of the head occurs, though in this case the subject is moving in the direction of the stimulus. It cannot, therefore, be compared to the type of reflex that occurs when a spinal animal withdraws the foot from a nocuous stimulus. Disagreeable and offensive verbal stimuli will also elicit this retraction reflex (Fig. 11), which—in contradistinction to the forward movement accompanying effort—appears, therefore, to have some of the specificity to nocuous stimuli that characterises the galvanic reflex. The respiratory changes do not differ, so far as I have been able to observe them, from those associated with effort. Fig. 12 is the record of two interesting tracings obtained, one as the reaction to a painful thought and the other to anger. The response in both cases is manifested as a flattening of the respiratory curve that we have seen reason to associate with increased muscular tonus. I am aware that many observers have attempted to demonstrate the existence of special forms of the respiratory curve associated with specific affective states, but the lack of uniformity in their results, which depend on measurement of the expiratory and inspiratory excursions, have failed to convince me that they are dealing with any specific reflex changes. The heart rhythm is accelerated in response to nocuous stimuli, but such acceleration, when it occurs, is of very short duration in response to a short-lived stimulus. With prolonged stimulation the cardiac rhythm is accelerated for the whole duration of the stimulus. Again, if the inferences drawn from measurement of the time relations of the cardiac cycle are to be trusted, it appears that the acceleration is due to depression of the vagal inhibitory and not to stimulation of the accelerator mechanism.

[1] Lecture I. appeared in THE LANCET of July 16th. Lectures III. and IV. will follow.

FIG. 9.

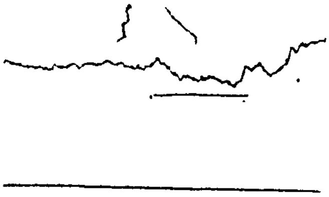

FIG. 10.

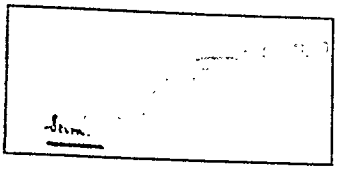
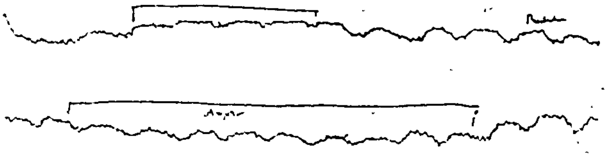


Photographic record of the increase in tonus of the arm muscles to a nocuous physical stimulus, recorded by the optical lever.

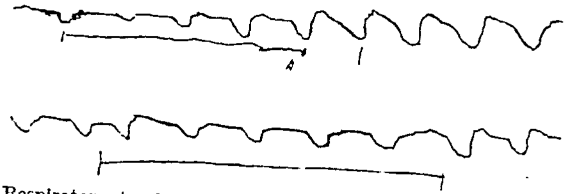
The evidence furnished by plethysmographic tracings of the vaso-motor reactions occurring in the limbs must be accepted with a certain amount of reserve. In the well-known Mosso plethysmograph as modified by Lehmann there are two possible sources of error which it is practically impossible to eliminate. First, a very small amount of displacement of the arm will cause a very marked effect on the plethysmographic curve and will be interpreted as an increase of volume if the arm be moved forward and as a decrease of volume if the arm be withdrawn ever so slightly from the plethysmograph. That such slight movements do occur and cannot be consciously guarded against is shown by the old experiments with an apparatus known as the "automatograph." In these experiments the partially flexed forearm is suspended in a cradle hung from a support. The movements of the cradle are recorded on an underlying drum and it is claimed that by this method it is possible to show that a disagreeable stimulus is responded to by retraction of the arm and an agreeable stimulus by its advancement. I have not adopted this method in my investigations, because I consider that it harbours many fallacies; but whatever the interpretation we may place on them, results thus obtained show that such movements certainly do occur. Another source of fallacy in the use of the plethysmograph becomes obvious from the evidence that I have submitted as to the diffuse increase in muscular tonus occurring as a bodily reaction in certain states of cerebral activity. Such an increase in muscular tonus must occasion an alteration of muscle volume simulating a vaso-constriction. I have dwelt on the shortcomings of the plethysmograph because we shall see later that results obtained from this instrument are the chief support for the assumption of a bodily response occurring in exactly the opposite direction to that elicited by nocuous stimuli. In order to avoid one source of error—that arising from slight movements of withdrawal or propulsion of the limb—I have designed a form of plethysmograph that has yielded fairly satisfactory results in these experiments. It is in essence a light metal drum covered at either end by a stout rubber diaphragm. There is a circular hole in each diaphragm, large enough to allow the passage of the arm whilst permitting a firm gripping of the limb by the thick rubber. The arm is thrust through both diaphragms so that the hand and wrist project beyond the further one, whilst the proximal end is a couple of inches below the elbow-joint. The drum is connected to a type of Brodie bellows recorder in which the bellows is replaced by a thin rubber "condom." The plethysmograph hangs freely on the arm, which is supported by two blocks at the wrist and elbow. Using an instrument of this type, which cannot be affected by any slight movements of the arm, in the direction of withdrawal or propulsion, I have obtained records of diminution of limb volume that are in accordance with those obtained by previous observers. It will be noted, however, that this arrangement of the plethysmograph cannot altogether neutralise, though it sensibly reduced, the error that arises from changes in muscle volume as a result of

FIG. 11.



Opposite movements of head. Forward with effort (recitation). Backward in response to offensive (verbal) stimulus. Respiratory and circulatory movements shown.

FIG. 12.

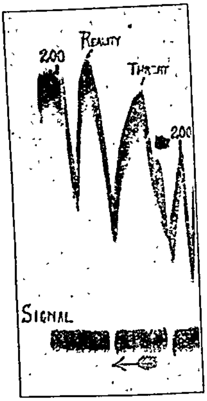


Respiratory tracings. The upper tracing shows effect of anger. The lower that of grief. The period during which the subject was indulging in the thought of the vexations and the painful experiences is indicated by the straight line below the tracing. (To be read from right to left.)

Fig. 1 shows a typical reaction as registered by the string galvanometer to a prick, the initial muscular start of which we shall have more to say is clearly seen. If now we proceed to use verbal stimuli instead of actual physical procedures we are using a type of stimulus belonging to the second category of our classification. The simplest form of verbal stimulus will be the threat of the application of a nocuous physical stimulus. Fig. 2 shows the responses to the threat of a prick and to an actual prick. Here we might hope to obtain some light on the relations of the two nervous mechanisms aroused. In this particular case you will note that the response is as great to the threat as it is to the act. I should like to be able to say that it was possible to correlate the mentality of my subjects with the relative efficiency of the two stimuli, but the results obtained from a large number of observations have been too inconstant. There are probably too many factors involved in the experiment—the degree of dramatic conviction with which the threat is performed, the attention of the patient, and the relative severity of the actual physical stimulus, must all be variables.

The threat to cause bodily discomfort is the simplest form of verbal stimulus. From this point onwards the stimuli may be elaborated by the representation of circumstances either past or present that are opposed to the well-being of the subject or are in conflict with the general tendency of his conduct—that is, stimuli such as will on the affective side evoke the feelings of grief or anger. So much for the galvanic response to external stimuli, but even more important is the galvanic response to stimuli whose immediate origin is in the autogenous neural processes of the subject. The spontaneous representation of some disagreeable or painful circumstance will serve equally well to elicit the galvanic reflex. Whether the subject recalls silently some past experience of a painful nature or whether he communicates it verbally to the observer the representation will in both cases evoke a diminution of skin resistance. We can now determine objectively the nature of the stimuli that will evoke the reflex without any further appeal to the evidence furnished by subjective inquiry. We note that one and all the stimuli have this property in common—their continuance is inimical to the well-being of the subject. Obvious as this is for the physical stimuli, it is no less clear when we consider the stimuli derived from outside verbal suggestion or from the representations evolved by the subject's own activities. The representation of an old pain must, if it be sufficiently vivid, involve all those reactions that occurred with the original stimulus. In so far as it falls short of representing them it falls short of being a vivid impression. I need hardly remind you that a representation must call into activity those nervous mechanisms that were aroused in the first instance, and that their necessary modification by subsequent neural associations constitutes the difference between the actual and the revived experience. In so far as the bodily response is concerned, the stimulus will in both cases be of the same nature as the initial physical stimulus, and from the objective point of view the reflex increase of conductivity evidences the same type of nervous activity. Fortunately for ourselves the representation can never or very seldom occur in anything approaching its first intensity. In many instances it cannot recur at all in a normally constituted organism.

FIG. 2.

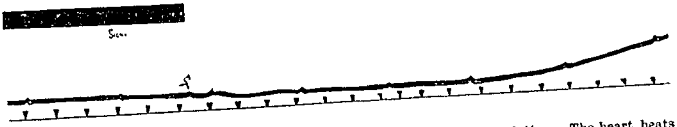


Galvanic response to burn and threat of burn. Graduations of diminution of resistance by 200 ohms.

THE GALVANIC REFLEX NOT UNDER VOLUNTARY CONTROL.

The completeness of representation is the test of the degree in which the activities of the organism as a whole have been modified by the original experience.

FIG. 1.



Galvanic response to a prick. Observe start (S) at the moment of stimulation. The heart beats are clearly shown. Time interval one-fifth of a second.

I try to recall an old toothache and I succeed in recalling concomitant experiences, but not a twinge of the original toothache. I recall a profound grief, and I shall feel much of my pristine pain and sorrow. Now the galvanic reflex distinguishes between these two types of representation, and this is what makes it so valuable for the objective study of cerebral activity; in our inner lives we are not always quite sure ourselves as to whether we have really any feeling about a subject—that is, whether it evokes a bodily resonance or whether it is merely a subject about which we think that we ought to feel strongly, whereas, in fact, it fails to arouse any bodily response. It is the objective demonstration of these two states that is furnished by the galvanometer. Anyone who cares to sit quietly by himself and recall past experiences whilst connected with the galvanometer circuit will learn much about matters that he has hitherto taken for granted. The resistance reaction is not under voluntary control; it is impossible to evoke it by simulation of affective states, such as a fictitious rage, nor can the mere recitation of emotional poetry, no matter with what emphasis it be declaimed, produce a reaction unless by some chance a phrase acts as a stimulus to evoke some association with a personal experience of affective import.

I will now pass on to consider some of the other aspects of this reflex that are of importance in affording information as to the relations of the mechanism of bodily reaction accompanying affective states to other nervous mechanisms. The reflex cannot be inhibited by any voluntary effort on the part of the subject. I have sought for evidence of inhibition of either of the response to physical or verbal stimuli in over a hundred subjects, but have never met with evidence of any direct voluntary power to either inhibit or modify the reflex. When the stimulus is not a maximal one the response may be modified to some extent by the activities of the subject at the time of stimulation. Fig. 3 shows the response to a moderately loud auditory stimulus, first, when the subject was expecting the stimulus; next, when he was engaged in mental arithmetic; and lastly (Fig. 4), when he was subjecting himself to a very painful faradisation applied to the sole of the foot. When I first obtained this result it seemed strange to me that the response to an irrevelant stimulus should be greater during the performance of arduous work than when the nervous system was keyed up to expect the

AN INSTRUMENT WHICH IS SET IN MOTION BY VISION

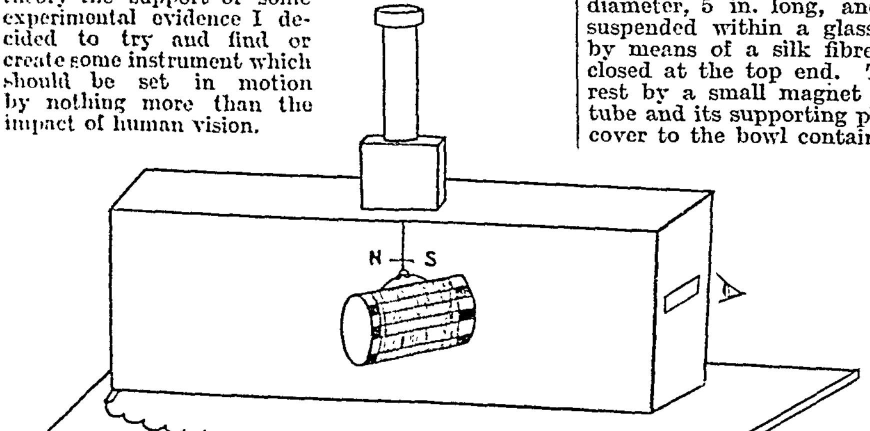
OR BY PROXIMITY OF THE HUMAN BODY.[1]

BY CHARLES RUSS, M.B. LOND., M.R.C.S. ENG.,
LATE PHYSICIAN, ELECTRICAL DEPARTMENT, MALE LOCK HOSPITAL, SOHO.

ALTHOUGH the force or ray I am about to describe emerges from the human eye, and is therefore physiological, the means I employ for its demonstration involve the use of electrical and magnetic instruments. The need for the scrutiny of experts in the science of physics was therefore obvious. I have had the great advantage of giving successful demonstrations of the work to experts in physics, including five Fellows of the Royal Society, besides Doctors and Bachelors of Science. None of these physicists found any mechanical or electrical fallacy which could account for the effects which I demonstrate as due to human vision. They do not so far identify the ray or force as being of a known or unknown type.

The fact that the direct gaze or vision of one person soon becomes intolerable to another person suggested to me that there might be a ray or radiation issuing from the human eye. If there is such a ray it may produce an uncomfortable effect on the other person's retina or by collision with the other person's ray; it is a fact that after a few seconds the vision of one or the other will have to be turned away at least for a short time. Numerous everyday observations and experiences seem to support the possibility of the existence of a ray or force emitted by the human eye, and in order to give my theory the support of some experimental evidence I decided to try and find or create some instrument which should be set in motion by nothing more than the impact of human vision.

FIG. 1.



The horizontal strips are of paper, to fix the coil wires on the celluloid of the cylinder.

Description of Apparatus.

Within a metal box (Fig. 1) I suspended a delicate solenoid made of fine copper wire. This solenoid was wound upon a cylinder of celluloid and suspended by a silk fibre (unspun silk) 14 in. long; the silk fibre was contained within a long glass tube mounted in the roof of the metal box. Its upper end was attached to a cork stopper and its lower end was furnished with a small metal stirrup into which the solenoid could be hooked. Attached to the stirrup was a small magnet consisting of a short length of steel wire magnetised by a steel magnet.

The box was 3 ft. by 8½ in. by 7 in., and lined with sheet aluminium. The far end of the box was closed by a sheet of window glass, and the near, or observer's end, was furnished with a thin glass or celluloid window which was also screened by a sheet of aluminium with a slot 3 in. long and 1 in. wide. A conducting wire connected the silk fibre with the aluminium of the box, which was earthed.

Method of Demonstration.

The solenoid was held steady by the magnet which naturally came to rest in the magnetic meridian (Fig. 1). If the human eye looks through the slot in the observing window and maintains a steady gaze at one end of the solenoid the latter will be seen to start into motion, which is usually away from the observing eye. If the gaze be now transferred to the true centre of the solenoid the latter stops, and if the vision is now applied to the opposite end of the solenoid the latter moves in a reverse direction to the motion first induced. This manœuvre may be repeated several times, each subsequent attempt being made only after the magnet has brought the solenoid to complete rest. Motion of the solenoid, though much reduced, was also obtained after interposing a column of water between the eye and the solenoid.

In view of later work it is possible that the solenoid is acting as one element of a condenser system—the air in the box being the dielectric.

Early in 1918 I had been impressed by the rapid induction of motion of the solenoid immediately after its replacement in its box or case. This activity soon fades to a minimal value which can always be obtained. Thinking that such activity might be due to some electrically charged state, I constructed some light condensers and tested the effect of vision on them. The form of condenser used was a celluloid cylinder having strips of lead or aluminium foil adhesively fixed to its inner and outer surfaces in symmetrical arrangement.

A large condenser of this type was made, 5 in. in diameter, 5 in. long, and weighing 10 g. It was suspended within a glass bowl 10 in. in diameter by means of a silk fibre enclosed by a glass tube closed at the top end. The condenser was kept at rest by a small magnet fixed above it. The glass tube and its supporting platform formed an airtight cover to the bowl containing the condenser (Fig. 2). The bowl was lined by aluminium foil except for small inspection areas at four diameter positions. For certain tests glass plates were also detachably mounted in a frame around the bowl with an air space between.

Although such a large condenser is only slowly set in motion by the human gaze, I decided to test the effect upon it of the body generally, and placed my hands on the glass case. I found the effect was much enhanced, for within about 20 seconds the condenser was set in rotation, and such motion might amount to 45° or even 90°. I noticed also that after producing this effect it only slowly returned to the zero position, in fact the return might require half an hour.

Time and Degree of Reaction.

The latent period and the degree of rotation obtained depend on the presence or absence of the extra glass plates which latter are also covered with foil. While producing this effect the operator's vision is assisting the rotation and also appears to determine the direction of the movement obtained—i.e., whether clockwise or counter-clockwise. To produce a rapidly acting model I suspended a sheet of celluloid 2½ in. by 4 in. inside a glass beaker. The celluloid was covered with gold leaf over an area of 2 sq. in. on each surface, and was suspended by a silk fibre and furnished with a control magnet. The glass beaker was covered inside and outside by aluminium foil except for inspection windows. If two fingers are placed on the vessel for two to three seconds and then removed the card is resistance of the skin is at its lowest. How far we are justified in assuming that cerebral activity is at its maximum at this time is very doubtful. Most people have the impression that their work is better performed either in the early morning or late at night, but this opinion is perhaps of little value. We judge of our work after all by much the same standards as those by which the world at large assesses our personal value. Everyone knows that the chief conditions of worldly success are great industry combined with a fair amount of stupidity, or—to put it less bluntly—with an absence of that self-criticism that so often destroys the power to accomplish things by leading us to inquire as to whether they are really worth doing. Similarly, the greater facility with which work is conducted at hours remote from the mid-day interval may simply be an expression of the abeyance of similar critical and inhibitory processes.

---

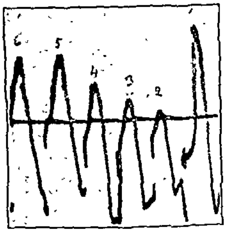
[1] A paper on this work and the instruments and effects were demonstrated by the author at the Ophthalmological Congress at Oxford on July 8th.

I have been unable, in spite of the large amount of material investigated, to secure any data as to a correlation between intelligence and the galvanic response that would appear to be sufficiently trustworthy to justify its inclusion in this review. In this connexion the work of Miss Waller appears to be highly important. She examined the galvanic responses of a class of 70 students to a series of standardised stimuli. The students shortly afterwards underwent an examination in physics. Correlating the marks obtained and the magnitude of the galvanic responses Miss Waller found that the average response of the higher placed half of the class in the results of the examination was greater than that of the lower half of the class. A further investigation on these lines is at present urgently needed.

IMPORTANCE OF LATENT REACTION TIME.

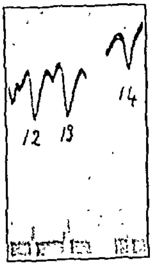
The latent time that occurs between the stimulus and the galvanic response is, as we shall see later, a matter of great importance in the elucidation of the significance of the bodily reactions. I have a large number of records, taken with the Einthoven galvanometer, which show the latent period in response to a variety of stimuli. To a physical stimulus, such as sound, the reaction time may be as long as 2·5 seconds, when the stimulus is a single loud tap on the table, whereas it may be as short as 0·8 second to a pistol shot; the latter figure was given by a young man with very large galvanic responses who was suffering from diabetes, a condition which we are accustomed to associate with hyper-excitability of the sympathetic system. *The duration of the response* is, in the case of a physical stimulus, conditioned primarily by its initial magnitude. As we have already noted, a response of great magnitude may be followed by an after-effect lasting for a considerable period, often three or four minutes. When we are dealing with verbal stimuli the latent period may be very long, the association processes necessary to evoke the response may be complex, and the duration of the response may be greatly lengthened owing to perseveration.

FIG. 6.



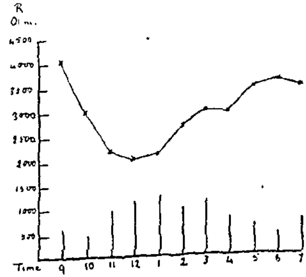
Response to series of break induction shocks. 2 coil at 10; 3 coil at 8; 4 coil at 6; 5 coil at 4; 6 coil at 2; 1 graduation 400 ohms. Final graduation omitted.

FIG. 7.



A conditioned reflex.—Upper line, the galvanometer, lower broad line the signal response. 12 and 13 are the last in a series of painful stimuli. For 14 the stimulus is short-circuited, but patient still responds on hearing the click of the key.

FIG. 8.



Graph showing rough correspondence through the day between skin resistance and galvanic reflex.

SPECIFICITY OF THE GALVANIC REFLEX TO NOCUOUS STIMULI.

I have now dealt with some of the main facts that have so far presented themselves from the study of the galvanic reflex, and I have especially dwelt on the nature of the stimuli that evoke this reflex. We have seen that to divide them into physical and psychical stimuli is from the objective point of view unjustifiable, since all these forms of stimulus have in common the property of injuring or inhibiting the normal course of vital activity. In future, in speaking of such stimuli, it will be convenient to assign to them collectively the same name that Sherrington has bestowed on those belonging to the physical class, and to refer to them as nocuous stimuli. The galvanic response is not the only type of response to nocuous stimuli that we know of. We have seen that it is an inevitable response incapable of any great degree of modification by other forms of activity, but this characteristic it shares with a number of other responses that we may study objectively. It has, however, one characteristic that at once makes its study of paramount importance in any objective investigation of neurosis, and that is that, alone of all the forms of bodily response that we shall study, it is specific to nocuous stimuli. It does not primarily occur as a bodily sign of the state of cerebral activity that we have considered already as effort.

OTHER OBJECTIVE SIGNS OF RESPONSE TO NOCUOUS STIMULI.

Now, in investigating further objective signs of the response to nocuous stimuli we shall find that we have met with all these signs in the study of effort. The diffuse increase of muscular tonus that we have already seen to be manifested both by movements of the extremities and by induration of the muscle occurs also as a response to nocuous stimuli of sufficient intensity. Fig. 9 shows a record of the movement of the foot caused by increased tonus of the quadriceps as a response to a painful stimulus. Fig. 10 is the photographic record of the increase in tonus of the arm muscles to a nocuous physical stimulus recorded by the optical lever. The movements of the head recorded by the method described in the previous lecture are, however, of a nature different from that of those elicited by effort. You may remember that the tonic response to effort was machine giving several thousand volts. At the moment of applying this electrical pressure to the plates the condenser goes into active rotation. After a moderate charge from the Leyden jar this swing subsides and the condenser comes to rest in the magnetic meridian position. If, however, the charge is large the condenser will be held for some minutes with its axis at right angles to the meridian. In this case the electric stress overpowers the magnetic pull. If the operator now looks into the open end of the condenser he will see its movement through 20–30°; when the eyes are closed it returns to its former position. Note must be made of the direction it takes. We know that left to itself the south end of the magnet will slowly turn towards the earth's south pole as the electric stress fades. If vision of the operator causes the south end of the magnet to go towards the earth's north pole I call it an anti-magnetic effect. If, however, his vision causes the reverse motion it has the same value as an effect provided it is found on removing the force (closing the eyes) that the condenser (and of course its attached magnet) returns to the stressed position at right angles to the meridian.

An important point must be made of the primary swing. It is vital to the production of the sensitiveness to vision of the condenser. If for any reason there is no swing then there will be no movement after vision is applied. In case the swing was operating by making in its passage through the air in the vessel a frictional charge on the condenser, I tested the matter another way. Taking a bar magnet and moving it round the glass case one makes the control magnet in the stirrup swing, and of course its attached condenser also swings. In this way no electric batteries or rods are used to set up the primary swing. The effect of sensitiveness to vision is still observable, though I think less actively than when using the Leyden jar method; but the experiment serves to emphasise the need of the swing and perhaps to throw light on the true nature of the vision effects. If repeated observations are made involving frequent charging of the plates the motion of the condenser becomes lazy under the static charge, but recovers after a little rest.

The electric charge will only hold for a few minutes on the jar and plates in damp weather. If dry conditions exist many vision effects may be obtained from only one charge. If, after charging, the condenser having come to rest, one discharges the jar by the insulated tongs, the condenser will show a rapid swing at the moment of electric discharge from the jar. By means of an accumulator and coil and spark gap I have tried to maintain the charge on the jar, so far with moderate success. As yet it is not easy to keep the condenser quite still, but when the apparatus is improved it will become independent of the humidity factor.

Controls and Precautions.—This system of the stressed plates is an extremely sensitive indicator of an electrostatic change. The operator must be still and seated behind a glass or celluloid screen so that no water vapour from nose or mouth can reach the glass case. His eyes are closed and no movements of limbs or other objects must disturb the vicinity of the electric field. When told by the assistant (or seeing by the spot of light) that the condenser is at rest, he will look at it and perceive that his vision has set it in motion, which can be measured on the scale. If the eyes are not opened or only the hand has been kept in the operating position there will be no effect. There must, of course, be no vibration of the room by traffic, or any mechanical disturbance of the supporting bench.

Darkness Tests.—I did four tests which seemed to give a positive result, but many more such tests would be required before a decision could be made on this point.

Probable Nature of the Effect.—There is an electrical change in the retina accompanying vision. There are also the electric changes in muscles when in action, and these will have associated electric fields. The eye muscles include the ciliary and iris and the oculomotor group. Whether the fields from these sources are adequate to account for the effects cannot be answered at present.

Heat.—Besides the evidence in the table the arrangements in Fig. 3 probably exclude this agency as a cause of the movement obtained.

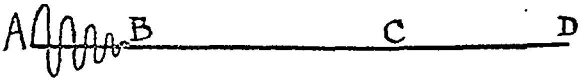
Electrostatic Force.—A force of this type cannot pass a fine metallic grid, and may therefore be considered unlikely to produce the activity observed.

Electromagnetic Force.—This group of vibrations includes a large number of rays ranging from the X ray to the wireless waves. The influence of light from the lamp seems suggestive of an influence of this type, but no critical tests have been done on these lines.

Summary.

Human vision can disturb the electrostatic state of an enclosed system. After the condenser has come to rest there must still exist a turbulence of the medium in all the types of experiment described. This turbulence appears to be reinforced or amplified by the applied vision, and is shown by (1) the activity shown by opening and closing the container; (2) the activity after rotating the condenser by the bar magnet; (3) the activity following the slight heating of the medium by the fingers on the guard plates; (4) the activity shown during the fading of the electric charges between the plates. Of course, at the time of operating these instruments by any of the above methods the turbulence is not sufficient to cause motion—i.e., the condenser has come to rest. Since the particles of any gas are always in motion it is probable that the effects of vision are only produceable when the turbulence of the medium is critical—i.e., of a certain intensity. If the turbulence has fallen below this degree the activity to vision is lost. This latter point is shown by the fact that activity to vision is lost long before the sparking power has disappeared from the Leyden jar (Fig. 4).

FIG. 4.



At point A the charge is applied causing the condenser's motion which has ceased at point B (1–2 minutes). Period B–C = the period for demonstration that the condenser is now sensitive to vision. This period lasts from three to fifteen minutes or more depending on the magnitude of the initial motion imparted to it at A and upon the dryness or humidity of the air. Sensitiveness to vision is lost at point C, and period C–D represents the further period during which a spark is still obtainable from the Leyden jar.

I do not propose to say more at present as to the probable nature of the force accompanying the act of human vision of which these experiments are the evidence. Instead I restrict the claim of my work to our possession of the instrument which affords the evidence of the force, and which is the limit of the title of this article. The only reference in the literature I have met was mentioned to me by a friend in 1919. It is a destructive criticism by Lord Kelvin of the work by a French physicist on the "Supposed New Force." After reading Lord Kelvin's paper one must, I think, endorse his view that the author failed to establish his views, as he would not even enclose his instruments to meet the objections of air or heat currents.[2]

During the course of this work, which has occupied spare time since December, 1917, I have had the advantage of criticism and suggestions by my brother Prof. Sidney Russ, Prof. A. Porter, F.R.S., Prof. Rankine, and others as to the physical aspects of my experimental arrangements.

---

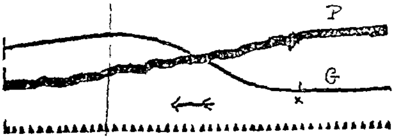
[2] On the Supposed New Force of M. J. Thore. By Lord Kelvin. (Phil. Trans., 1887, vol. clxxviii., p. 451.)

increase of tonus. The only method of plethysmographic recording that would be free from both these errors is that adopted by Weber who used an ear plethysmograph. I confess that the extremely disagreeable features of this method, which involves the working of large amounts of vaseline into the hair, have prevented me from proposing its use to the subjects of my experiments. *Fig. 13* shows a photographic record of the plethysmographic and the galvanometric responses to a nocuous stimulus. It will be observed that the latent period is identical in the two forms of response.

RESPONSES TO BENIGN STIMULI.

Now so far we have considered the bodily response to nocuous stimuli, that as to stimuli that tend to disturb and destroy life, and we have, moreover, noted that the sensory concomitant of such responses has been a feeling of an unpleasant nature. We may now fairly envisage the question as to what are the responses to stimuli that tend to further and perfect life—what we will call benign stimuli—which so far as they have any sensory reaction affect us pleasantly. Since the galvanic reflex is the only response that we have so far been able to study that is specific to nocuous stimuli and is not elicited by effort, it is to this reflex that I shall first turn for an answer. I have found that to stimuli of a benign nature there is either no response at all or else a slow increase in resistance occurs; but this slow alteration of resistance is only to be noted when the preceding state is one of the low resistance that we consider to be indicative of general bodily activity. If, after a series of painful or vexatious stimuli the attention of the subject be diverted to more pleasurable matters, the lowered resistance rises gradually until a point above the initial neutral state has been reached. If a hungry subject be given a satisfying drink and appetising food the resistance will show a slow increase. If a subject who has taken up his position, rather dreading a series of irksome experiments with painful electrical shocks, be told that for that séance the observer only purposes to take some simple pulse records this welcome news is followed by a slowly developing increase of resistance. The response with which we are dealing has none of the brusque and decided characteristics of the galvanic response to nocuous stimuli; its slow and variable onset and the indefinite nature of the stimuli that tend to arouse it do not allow of any formulation of the latent period of this increase of resistance. I have never seen it occur under five seconds with the type of stimulus that I have been considering. This indefiniteness may partly be attributed to the method of experiment—to attempt to produce such a violent reaction as that which we characterise as joy is, under the conditions of the somewhat dreary experiments conducted in the laboratory, a practical impossibility. The muscular tonus response that has been found to be evoked by both effort and nocuous stimuli cannot, of course, give the same clear-cut answer as the specific galvanic reflex, but the tendency is in the same direction. When the painful stimulus is removed the muscular hypertonus relaxes slowly, and ultimately relief from pain is characterised by a far higher degree of relaxation than that found at the onset of the stimulus. This relaxation is well shown in Fig. 10. The pulse-rate becomes slower after the nocuous stimulus, and this slowing may be observed in the galvanometer curve of reaction to a pistol shot (Fig. 1). In this case, before the stimulus was administered, the pulse-rate had been more rapid than normal, and immediately after the stimulus was still further increased for a couple of beats and then becomes slower. We have here, therefore, a complex result of two different forms of excitation—the suggestion that a disagreeable experience is to be undergone, and the stimulus itself. It is characteristic of the cardiac response that its duration is almost confined to that of the stimulus itself; hence the slowing that occurs after relief from the stimulus may be actually present while the other forms of response, such as the galvanic reflex, are still in progress. The response, therefore, to a benign stimulus is a diminution of organic activity. Philosophers of all ages have frequently drawn attention to the superior efficacy of pain as a vital stimulus. So far as an objective study of these reactions has taken us the reaction to a benign stimulus is only presented as a relief from the previous activity occasioned by a nocuous stimulus. It is not possible here to follow the line of thought suggested by these experimental results and to inquire whether benign stimuli with their pleasurable sensory aspects should not be considered merely as an interruption of the stream of nocuous impulses that spur the organism to activity. Theophrastes, quoting Anaxagoras, tells us that to feel is to suffer *ἄπασαν αἴσθησιν μετὰ λύπης.* If we substitute for the definite presentation of the specific sensation the vague affective state that accompanies a nocuous stimulus, the dictum of the early Greek philosopher holds true. Pain is the fundamental fact and pleasure nothing but relief from pain. It will be objected that moments of great joy are certainly accompanied by the exhibition of bodily activity—the winning side cheer and clap their hands—the dog will bound with pleasure when he recovers his lost master. This difficulty is easily dealt with. Such exhibitions of activity are not specific responses to the benign stimulus. They are not directed to the prolongation or the curtailment of the bodily reaction to the stimulus. They appear to be a compound of at least two factors, the discharge of certain reflex activities that have been inhibited by the tension of the muscular system, and the appearance of a specific type of nervous activity—the instinct to communicate with others.

FIG. 13.



Simultaneous record of galvanic (G) and plethysmographic (P) responses to a prick, x.

A great deal of confusion has been occasioned by statements to the effect that the vasomotor reactions studied by the plethysmograph show an active dilator response to pleasurable stimuli which is in every sense the antithesis of the constrictor response to disagreeable stimuli. This statement, which is unfortunately copied from text-book to text-book, is based, as Shepherd has shown, on a very few experiments of Lehmann, which have not been confirmed by other observers. Using my own modification of the plethysmograph I have only succeeded in demonstrating the same type of slow return to the normal state from a vasoconstriction due to a nocuous stimulus that we have seen to occur with the galvanic response.

The objective study of these bodily responses to stimuli possessing feeling tone lends some support to the tridimensional theory of feeling of Wundt and the later somewhat similar view advocated by Royce. Without entering into any discussion of these questions it is still important for the understanding of neurotic disturbances to realise the plurality of the bodily responses that go to the make up of an affective state.

DONATIONS AND BEQUESTS.—By will the late Mr. Frederick Ernest Muntz, of Umberslade Hall, Warwick, has given among other bequests, £2000 to the Birmingham and Midland Free Hospital for Children; £1000 each to the Home for Incurables, Leamington, the Institution for Deaf and Dumb Children, the Royal Institution for the Blind, Birmingham University, and the Institution for the Feeble Minded, Knowle; and £500 to the Birmingham Y.M.C.A.

all-important, and must be adjusted with scrupulous care. Phenolphthalein was used as indicator in the titration, which was carried out at boiling point. The plates having been incubated for 24 hours, suspicious colonies were transferred to Russell's double sugar agar, in which Andrade's reduced fuchsin was used as indicator. On this medium it is usually possible to observe gas formation after 12 hours' incubation, and so to weed out the non-dysentery organisms.

The growth obtained on Russell's medium was then agglutinated macroscopically on a slide with Dreyer's Oxford Flexner serum, the reaction, if positive, appearing in about 15 seconds. If agglutination appeared thus the case was treated as a positive. It was therefore possible to send out a laboratory report on the specimens of fæces well within 48 houss. This rapidity of diagnosis is extremely important from an epidemiological point of view. As a confirmatory test the organisms were subcultured and grown on the "sugars," and, in addition, were agglutinated macroscopically with Dreyer's Oxford serum to full titre. It was found in practice that no organism which passed the rough test failed to pass the more detailed and delicate one.

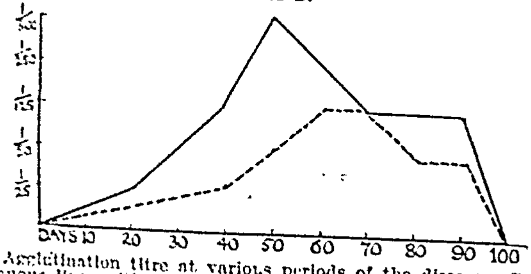
The bacillus was non-motile and Gram-negative, and, while producing acid without gas on glucose and mannite, it left lactose and saccharose unchanged. It is interesting to note that from two of the cases of diarrhœa from which the Flexner type bacillus was not isolated, *B. pyocyaneus* was obtained in almost pure culture. In the case of one patient who died, although there was extensive ulceration of the intestine reaching practically as high up as the duodenum, only cultivations from the rectal contents yielded the Flexner type bacillus, none being present in cultures taken from the higher parts of the intestine or the internal organs.

Agglutination Tests.

Frequent agglutination tests were carried out on the serum of all those patients whose fæces had been proved positive bacteriologically, and also on some cases whose fæces did not yield positive results. Dreyer's standard Oxford antigen was used in all cases, and latterly another Flexner type antigen, kindly supplied to us by Prof. Dudgeon, of St. Thomas's Hospital, was used in addition.

Several facts of fundamental interest were collected. It was found that, with Oxford antigen, the first trace of agglutinins appeared at the end of the sixth week, and that agglutinins had disappeared at the end of the fourteenth week; while with Prof. Dudgeon's antigen agglutination began to appear about the beginning of the fourth week, and had disappeared at the end of the fourteenth week also. Maximum agglutination was obtained with Oxford antigen between the eight and tenth week, and with Prof. Dudgeon's antigen in the seventh week (Chart 2). No case in which the fæces were negative bacteriologically gave a positive agglutination with either antigen. Many agglutination tests were performed; using the organisms isolated from the cases themselves as antigen. The curves thus obtained conformed roughly with those given by Oxford antigen and that of Prof. Dudgeon.

CHART 2.



Agglutination titre at various periods of the disease. Continuous line, with Dudgeon's antigen. Interrupted line, with Dreyer's antigen.

Shaw Bolton and Nabarro[2] have carried out extensive investigations on the agglutinins in dysentery. They state that a positive reaction occurs early in the disease, and that many apparently healthy persons, who are not known to have suffered from dysentery, give a positive reaction, thus raising the question of the possibility of unsuspected carriers. Our results are not in accordance with their findings.

Conclusions.

1. It is of paramount importance that the fæces of all cases of clinical dysentery and diarrhœa be examined in the laboratory. 2. Having regard to the fact that primary attacks and relapses may be so slight as to pass unnoticed, and the possibility of every case remaining a chronic carrier, very strict observation and a system of permanent isolation are necessary in order to prevent the spread of the disease. 3. Agglutinins are present in the blood of affected patients only after the fourth week of the disease, and therefore agglutination tests are of little diagnostic value.

SEROLOGICAL TYPES OF PNEUMOCOCCI IN LOBAR PNEUMONIA.

A STUDY OF 100 CASES.

BY FRED. GRIFFITH, M.B., CH.B. VICT., D.P.H.

(From the Pathological Laboratory of the Ministry of Health.)

THE study of the immunological types of pneumococci has been shown by the workers of the Rockefeller Institute in America and by Lister in South Africa to be of great importance in the prevention and treatment of lobar pneumonia. The existence in this country of the types defined by the American workers had been established, but the information which has been published in respect to their distribution is still somewhat scanty.[1] I therefore propose to contribute my observations on the serological characters of strains from 100 cases of lobar pneumonia which I have classified according to the American method. The standard type strains upon which the classification is based were presented by Prof. Flexner to Sir George Newman, who made them available for the purposes of this inquiry.

Preparation of Monovalent Agglutinating Serums in Rabbits.

Adult rabbits were used, being immunised by the intravenous inoculation of pneumococci in ascending doses. The suspensions of pneumococci were obtained by centrifuging broth cultures, the deposits from which were generally diluted with some uncentrifuged broth culture. The inoculations were made on three consecutive days and were followed by a rest of from five to seven days. For the first three series of inoculations the culture used was killed by heating to 60°C. for half an hour, and was prepared freshly for each series. The immunisation was continued with living culture, beginning with a fraction of a cubic centimetre of broth culture and gradually rising until the whole of the deposit of 20 c.cm. of broth culture was administered at a dose. The total period of treatment was 10 weeks; the animals were bled within 10 days after the last inoculation. The serums were tested upon pneumococci from broth culture suspended in salt solution, and gave for types 1 and 2 a titre of 1:320 and for type 3 1:640. These serums were re-tested after being preserved in a sterile condition in the ice-chest for 10 months; they showed no appreciable diminution in potency. No reaction with heterologous strains—e.g., type 1 serum against types 2 and 3, &c.—was obtained in dilutions of 1 in 20.

In a second series of rabbits some observations were made on the progress of immunisation. Treatment commenced with suspensions of heated broth culture, preserved with 0·5 per cent. carbolic acid, and continued for five weeks, inoculations being made on three successive days, followed by an interval of rest. The serums then showed titres ranging from 1:20 to 1:40 for the four type 1 rabbits, and 1:4 only for the three type 2 animals. The treatment was continued, but with a fresh heated suspension of each type;

seen to rotate towards the side of the hand used to touch the vessel wall.

Possible Influence of Heat.

At this point I will deal with the obvious possibility of heat being the cause of the motions described. Heat from the hands and body proximity is, of course, reaching the apparatus, and we know the delicacy of the heat-recording instruments at the command of the science of physics. I did not attempt to measure this heat, but decided to apply heat to my apparatus. The results are shown in the following table, and I think the inference is that heat is inadequate to explain the effects observed. I found the effects much reduced, though not abolished, after *surrounding the condenser by a jacket of water, paraffin, or methylated spirit.*

Heating experiments of the cases containing the condensers were undertaken in two ways: (1) Radiant heat from one or two candles 3 inches from the glass plates surrounding the large condenser (Fig. 2) were almost entirely negative up to periods of six minutes; (2) water heated to the temperatures shown in the table was placed in metal vessels against the glass plates, which were covered also with metal strips and the areas of contact arranged were several times as large as the contact area of the human fingers.

After placing the hands on the metal area of the guard plates the condenser moves after 30 seconds and usually travels through from 10° to 15° within two minutes. In the hot-water experiments there was no vision applied.

* Temp. at end of experiment = water 77° and 73° C.; hot sides of bowl, 17·2°; cold sides of bowl, 13·3°. A = Anti-clock.

Effects of Vision Alone.

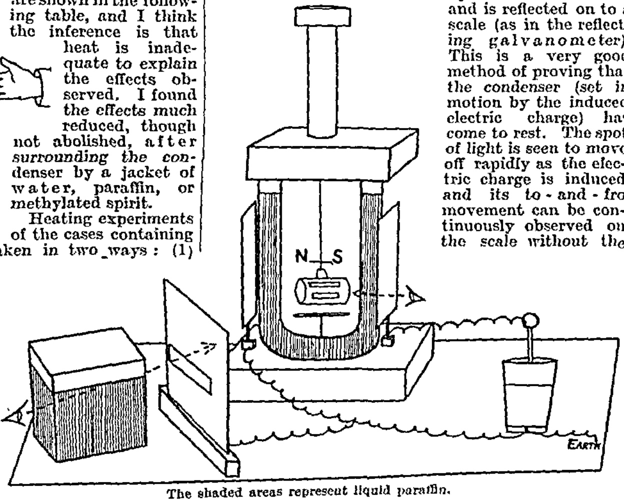
Glass Rod Method.—Remembering the activity referred to when replacing the coils and condensers in their cases, I decided to try the effects of charging them *electrically by induction. If a glass* rod rubbed with silk approaches the glass case (Fig. 3) the condenser goes into rotary motion, and when this has ceased it comes to rest in the magnetic meridian.

It is now sensitive to vision, and may, therefore, not be looked at until it has come to rest. This moment may be ascertained by a glance at its reflected image in a mirror 10 feet away. When at rest its sensitiveness to vision only lasts about 30 seconds, depending on the force of the initial swing given by the rod's approach. If the eye looks through the fluid and slot at the optimum period it will see the condenser go into active rotation which may amount to 30° or 45°. The sensitiveness is brief and can only be renewed by re-charging with glass rods.

This method is one I used at first, but it is difficult and not quite satisfactory when demonstrating to others; I have therefore improved upon it.

Spot of Light Method.—A small mirror is fixed to the stirrup on the end of the silk fibre. This mirror moves with the stirrup and its attached condenser. Light from a lamp near by falls on the mirror and is reflected on to a scale (as in the reflecting galvanometer). This is a very good method of proving that the condenser (set in motion by the induced electric charge) has come to rest. The spot of light is seen to move off rapidly as the electric charge is induced and its to-and-fro movement can be continuously observed on the scale without the eyes being directed at the condenser. When the spot of light has been seen to come to rest it will be found that human vision now directed at the condenser sets it, together with the spot of light, into rapid motion, which may be so large as to take the latter quickly off the scale. Special caution is, however, needed in connexion with this method, for I failed repeatedly in trying to use it until I had noticed that no light from the lamp must be allowed to fall on the condenser. This is easily managed by interposing a screen of black paper or the equivalent between the lamp and the condenser. The little mirror in the stirrup is above the level of the condenser, and the small beam needed to give the spot of light is easily provided and focussed by means of a lens if desired.

FIG. 3.



The shaded areas represent liquid paraffin.

Charge Plates Method.—In Fig. 3 the method is shown. Two metal plates are embedded in blocks of sulphur and mounted by the sides of the instrument. One is connected to the outer coating of a Leyden jar and is also connected to earth. The other plate embedded in the insulating sulphur is connected to the inner coating of the jar by a spring or chain and cap contact with the knob of the jar. The Leyden jar is charged by contact with an electrical friction

This work has been made possible by the kindness of the medical officers and pathologists of various Poor-law institutions in providing material, and I wish to express my indebtedness to Dr. J. R. Perdrau, Dr. R. C. Harkness, Dr. W. Brander, and many others. I am also indebted to Prof. E. E. Glynn, who has kindly sent me specimens of each of the three American "fixed" types which he has isolated from cases of pneumonia. These I have found to conform to my own standards.

THE DIAGNOSIS AND TREATMENT OF STERILITY IN THE MALE.

By KENNETH M. WALKER, M.A. Camb., F.R.C.S. Eng.,

IN CHARGE OF VENEREAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL; SURGEON WITH CHARGE OF GENITO-URINARY CASES, MILLER HOSPITAL FOR S.E. LONDON.

Although the subject of sterility has long attracted the attention of the medical profession, and although much has been written on its causes and treatment, it cannot be claimed that the practical results obtained up to the present are satisfactory, or that when consulted for sterility the medical man of to-day can hold out to his patient much more hope of successful treatment than the medical man of 50 years ago. Our failure in this respect is in the main due to our ignorance of the physiology of reproduction. Attention has been focussed almost entirely on questions of anatomy. The discovery of a contracted cervix or of a retroverted uterus is hailed with delight by the medical man consulted for sterility. Even although he can recall innumerable cases of conception in women suffering from similar disabilities he feels that retroversion is an abnormality, and that, as it is a condition capable of correction, the first essential to treatment is the remedying of the retroversion. So also is it in the case of the male. The husband of a sterile wife is examined for gross abnormalities. If the external genitalia appear well formed and spermatozoa are discovered in the semen he is passed as normal.

In text-books dealing with sterility in the male, hypospadias, epispadias, cryptorchism, exstrophy of the bladder, stricture, and impotence are given as causes of sterility. In actual practice such conditions, with the exception of the last-named, are seldom encountered, and therefore as causes of sterility their importance is trifling. Yet, as all modern statistics show, the male is frequently the partner responsible for a sterile marriage. If, therefore, the possibility of male sterility is to be excluded something more than a search for gross abnormalities must be undertaken. The examination must be as exact and as thorough as modern methods will permit. It is with an idea of indicating the lines along which such an examination should be made that the following has been written.

Method of Investigation.

The investigation of the male suspected of sterility resolves itself into two parts: a careful overhauling of the genital tract, and an analysis of the seminal fluid. At the preliminary visit an inquiry is made into the past history, special regard being paid to infection, venereal or otherwise, and to the existence or not of any abnormalities or difficulties in the sexual life of the individual. Although it cannot be claimed that the examination of a condom specimen is an ideal method of investigation it nevertheless furnishes information of great value. In connexion with this examination the following points should be borne in mind:—

1. The specimen should be as fresh as possible. Although mobile spermatozoa may occasionally be found ten hours after emission little reliance can be placed on an examination in which so long an interval has been allowed to elapse. It must also be remembered that the optimum temperature for the conservation of mobility is comparatively low. If active spermatozoa be placed in an incubator at 37° C. movement will, as a rule, have disappeared at the end of two hours. At 27° C. mobility is more likely to be retained.
2. A period of abstinence from sexual relations of a week's duration must be prescribed previous to the examination.
3. In the event of the first specimen proving abnormal at least two subsequent examinations must be made before an adverse report is issued. It not infrequently happens that after failing to find spermatozoa on two occasions an investigator will discover their presence in the third specimen submitted for examination.

The semen to be regarded as satisfactory must contain a plentiful supply of well-formed and mobile spermatozoa, and must reveal no abnormal elements such as pus cells, indicative of an unhealthy condition of the genital tract. In considering the character of the spermatozoa and estimating the fertilising efficiency of the semen the following points must be noted:—

1. The number of spermatozoa seen in an average field.
2. The percentage of spermatozoa perfect, imperfect, or deformed.
3. The percentage of spermatozoa that are mobile, their degree of mobility, and the time during which mobility persists.

Oligozoöspermia.

Lode has estimated that about 260,000,000 spermatozoa are emitted in one ejaculation. The faintly acid reaction of the vaginal secretions and its abundant flora are not conducive to the long life of the spermatozoa, so that but few reach the cervical canal. It is easy to see, therefore, that a diminution in the number of spermatozoa in the semen lessens the chance of fertility. The number of spermatozoa found in the semen is reduced in extreme youth and in old age. It is, moreover, subject to variation in the same individual according to fluctuation of general health, and in all probability to seasonal changes. Although man has escaped from the rigid œstral cycle, to which the majority of the lower animals are bound, it seems probable that his freedom is not absolute. When one recalls the enormous increase that takes place during the breeding season in the size of the testes and accessory glands of the sparrow and the hedgehog, it would appear anything but surprising that the sexual activity and fertility of man should also show some tendency to a seasonal fluctuation.

Amongst the causes of a pathological oligozoöspermia are inflammatory conditions of the genital tract and their sequelæ, sexual excesses, certain diseases of the nervous system (both functional and organic), chronic alcoholism, and, indeed, any condition causing a marked impairment of the general health.

Azoöspermia.

The consistent absence of spermatozoa from the semen may be due to one of two causes: (*a*) the existence of a mechanical obstruction in the genital tract; (*b*) the absence of spermatogenesis in the testes.

Diagnosis.

Before any prognosis can be given or any treatment suggested it is essential than an exact diagnosis should be arrived at, and the case allocated to one of the above two classes. For this purpose the genital tract must be carefully overhauled. The situations at which obstructions are usually found are at the lower pole of the epididymis and in the course of the ejaculatory ducts. These obstructions are almost invariably the sequelæ of old inflammatory reactions, and in 60 per cent. of cases are due to gonorrhœa. Next in importance to gonorrhœa as a cause of obstructive sterility comes tuberculosis. Even when one epididymis alone has been attacked azoöspermia is likely to result, owing to involvement of the prostate and vesicles. Out of 22 cases of genital tuberculosis examined by the author, 20 gave indications of prostatitis or vesiculitis, and were therefore liable to obstruction of the ejaculatory duct. It is not claimed that these prostate lesions were necessarily tuberculous in nature, but merely that the prostate or vesicles gave evidence of chronic inflammation, and were, therefore, capable of exercising an unfavourable influence on the fertility of the patient. Syphilis as a

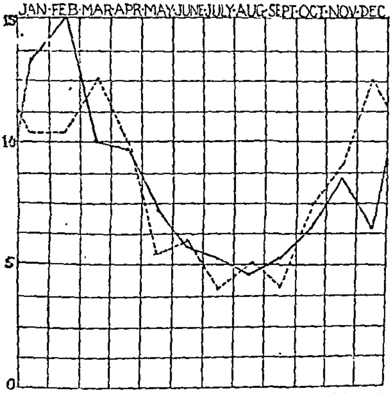
THE ÆTIOLOGY OF BACILLARY DYSENTERY IN ASYLUMS.

By W. S. DAWSON, M.A., M.B. Oxon.,
M.R.C.P. Lond., D.P.M.,
AND
W. MOODIE, M.D. St. And., D.P.M.,
ASSISTANT MEDICAL OFFICERS, CLAYBURY MENTAL HOSPITAL.

The question of asylum dysentery is of such interest to those concerned with the care of the insane that from time to time much useful investigation has been undertaken in the hope of establishing its ætiology. The present state of our knowledge may be summed up in the words of Tidy, who says, in his "Synopsis of Medicine," "No specific organism is present, but bacteriological and serological investigations have indicated bacilli of the Flexner group." The study of a small series of cases which occurred in Claybury Mental Hospital during the earlier months of this year has yielded such definite results that it appears worthy of special note.

In 1900 Mott and Durham made a comprehensive study of dysentery in Claybury, and, although they were unable to isolate any specific organism, they showed clinically and post mortem that it resembled the bacillary type of the disease rather than the amœbic. Many observers have from time to time claimed to have discovered amœbæ in the stools of patients, but their results require confirmation.[1] In spite of all efforts to control it, dysentery has in the past been the cause of a large amount of the sickness in asylums, as well as a considerable percentage of the mortality. Thus, during the year 1919, in 80 county and borough asylums 1722 cases of dysentery were notified, and of these 384, or 20 per cent., died, forming 3 per cent. of the total number of deaths.

CHART 1.



Continuous line shows monthly incidence of cases of dysentery in 80 county and borough asylums expressed as percentages of the total for 1919. Interrupted line shows monthly incidence of cases of dysentery in Claybury female wards, 1909–1920.

Contrary to the accepted view that dysentery is a disease of hot weather and is generally spread by flies, the highest incidence of cases in Claybury occurs during the winter months. Chart 1 is constructed from a monthly average of cases occurring in the female wards during the years 1909 to 1920. The published statistics of the Board of Control for all the asylums of England and Wales show roughly a similar incidence.[2] Figures from the Ministry of Pensions and the Army for 1920, kindly supplied to us by the Ministry of Health, show a remarkable similarity to our own, over 50 per cent. of the total number of cases being reported during the period of January to April. It would therefore appear that asylum dysentery spreads not so much through flies as through some more direct method from patient to patient, especially during the winter months, when the patients are confined within doors for a greater number of hours per day on account of climatic conditions.

Carriers.

It is usually taken for granted that certain patients who have suffered from dysentery become carriers, and are therefore capable of disseminating the disease for a more or less protracted period after the acute stage has passed. One of our patients, who has relapsed seven times in eight years, is probably a carrier. She has been free from acute symptoms for several months, and examination of her fæces at the present time fails to reveal the presence of an organism of dysentery. On the other hand, slight transient attacks, which may pass unnoticed in a previously healthy patient, may yet be of great danger as a source of infection. For example, a patient who was confined to bed for mental reasons on one occasion passed a loose motion in which a small quantity of blood was noticed. This was kept for examination, and produced a Flexner type bacillus on culture. The serum of this patient, at the end of the eighth week, agglutinated Prof. L. S. Dudgeon's antigen in a dilution of 1 in 125.

The question of relapsing cases who are probably carriers has been raised, and it is interesting to note in this connexion that of 590 patients who suffered from dysentery in Claybury during the past 12 years, 18 per cent. relapsed once, 6 per cent. twice, and 3 per cent. three times. In mild cases the dysentery bacillus disappears from the fæces in a few days, and the patient has apparently made a rapid recovery. We have, however, noted that not infrequently a relapse has occurred within a few weeks after the fæces had been reported negative on several occasions. A patient who has had an attack of dysentery thus remains a possible source of infection to others, especially as mild, transient relapses may pass unnoticed in patients who are too demented to appreciate slight irregularities in their bodily functions.

To ensure the complete eradication of the disease from asylums, it would therefore appear necessary to carry out a very complete scheme of permanent isolation, and to treat every dysentery case as a potential permanent carrier. This principle is at present applied in Claybury, and all cases in the epidemic here reported occurred in wards where patients known to have previously suffered from dysentery were housed.

Bacteriology.

Seven cases occurred during the first four days of the outbreak, and from the fæces of all of these a bacillus of the Flexner type was cultivated. The patients affected were isolated in single rooms, and a strict watch was kept for any suspicious cases of diarrhœa, several of which occurred during the subsequent two months, and were investigated. During that time an identical bacillus was found in five more cases. The system of isolation of positive cases was persisted in, and, at the time of writing, no case of clinical or bacteriological dysentery has occurred for over a month.

The method employed in examining the fæces was as follows:—The specimen was taken from the motion and sent to the laboratory on a swab similar to a throat swab. This was found to be a very handy, clean, and efficient method of collecting specimens. If preferred, the swab may be introduced into the rectum of the patient, and the mucus from the wall of the rectum thus obtained directly. The latter method was employed extensively during the war, and was found to be excellent. It also has obvious practical advantages.

MacConkey's medium was used for plating, of a reaction of + 4 acid. The reaction of the medium is

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

EXTRUSION OF A RENAL CALCULUS

CAUSING A SINUS IN THE LOIN.

BY H. J. ORR-EWING, M.C., M.D., B.S. LOND., M.R.C.S. ENG.,

ASST. MED. OFFICER, ENGLISH MISSION HOSPITAL, JERUSALEM.

THE following case is recorded as unusual, and presenting special features of interest:—

History.—N. G., a native Arab village woman, aged about 30, came to hospital from Nablous on Oct. 18th. She stated that she was suffering from a wound in her back, which had been discharging for a year. She said that she knew of no cause for this "wound"; no history was obtainable of injury, acute illness, pain, or disability of any kind. In the Moslem idiom, she stated that it was "Min Allah"—in other words, it had developed spontaneously; apart from the wound she felt very well.

On examination she proved to be a fine, apparently healthy woman, who had all her life been accustomed to the hardest manual labour in a country where all the heavy work is done by women. Nothing abnormal was discovered in chest or abdomen; the spine showed no tenderness, deformity, or rigidity; the urine was quite normal, specific gravity 1015, slightly acid, no albumin, no blood, no casts, no deposits of any kind visible to the naked eye. Over the left loin, about 2 in. from the middle line, at the level of the first lumbar vertebra, was a wound, or sinus, discharging yellow pus of a thin consistency; there was no urinary element in the discharge. The sinus passed downwards and outwards; a probe was inserted and a foreign body was discovered lying 1 to 1½ in. from the surface. This body felt like dead bone. A provisional diagnosis of tuberculous abscess was made. The difficulty lay in the origin of the "dead bone"; the wound was above the crest of the ilium, quite a distance from the vertebra, and the twelfth rib could be traced intact above. The patient was admitted to hospital, where her temperature for three days remained subnormal and her pulse-rate 70–80.

Treatment.—On the 22nd she was anæsthetised and a transverse incision was made with a view to enlarging the opening of the sinus. A probe was now passed beyond the foreign body, and the sinus found to go directly in the direction of the left kidney. The supposed bone was grasped by necrosis forceps and pulled out through the enlarged exit wound. It was found to be a large renal calculus, roughly circular in circumference, and somewhat loaf-shaped. It was encrusted thickly with what was presumably uratic substance, and the interior, I imagine, was uric acid (I did not cut it up owing to the patient's desire to possess the trophy); the diameter of the stone would be about five-eighths of an inch. The sinus was then thoroughly cleared, packed with iodoform and drained, the remainder of the wound being sutured. She has made a good recovery: in no way affected by a temperature of 101° F. the night after the operation, and 103·5° the next night; this proved upon blood examination to be due to the ubiquitous malarial parasite, and speedily yielded to appropriate treatment. The sinus is healing up from the bottom, and although once in the daily dressing I washed out of the wound some gravelly material, there has not been the slightest urinary odour, nor any evidence of the presence of urinary matter in the discharge.

Remarks.—The woman, who was carefully questioned in view of the findings above, still denied any history of pain such as renal colic, and stated that she never had any pain during micturition. never suffered from frequency, nor had she had any passage of gravel. Her obstetric history had been uneventful. The history in these cases is notoriously inaccurate, but there seems no reason to suspect deception. The patient is an exceptionally intelligent woman for her class and race. In these days such cases must be fairly rare; even in Palestine the native usually seeks medical advice comparatively early. Nothing either in the history, symptoms, or urinary investigation led us to suspect the renal cause of the trouble; true, there were difficulties in the spinal caries diagnosis, but tuberculosis, especially of bones and joints, is very prevalent amongst the Fellaheen and Bedouin Arabs, and to suspect renal calculus in the absence of any indications of an affection of the kidney seemed to be uncalled for.

I have no access to the literature of similar cases, but I seem to remember that most, if not all, of the recorded cases have given rise to suspicions as to their causation, by some, at any rate, of the symptoms and signs so conspicuously lacking in this case. It was quite a minute before I realised that I was looking at a renal calculus, and not at the possible result of an attack with a slung stone from the rear.

A FURTHER NOTE ON THE

LYMPHOIDOCYTE AND ITS CLINICAL SIGNIFICANCE.

BY A. KNYVETT GORDON, M.B. CANTAB.,

MEDICAL SUPERINTENDENT OF THE VIROL RESEARCH LABORATORIES.

IN a previous communication to THE LANCET of July 19th, 1919, I recorded the finding of lymphoidocytes—which are regarded as the parents not only of leucocytes and lymphocytes but of red cells also—in the circulating blood in fatal illnesses other than primary anæmia. I have since extended these observations, and give a brief summary of the results.

Twenty-six patients were selected, who were described as moribund, and who certainly appeared to be in extremis. Lymphoidocytes were found in 24, associated in every case with a marked leucopenia and the presence of leucoblasts—the parent both of leucocytes and lymphocytes—and in six cases with a few myelocytes also. The diagnosis is as follows: Diabetic gangrene 3, carcinoma with generalised metastases 3, senile decay 2, advanced tuberculosis 6, cardiac valvular disease with broken-down compensation 7, severe malaria 1, relapsing fever (with presence of the characteristic parasites) 2. All of these subsequently died. The two remaining somewhat unexpectedly recovered, and the lymphoidocytes could no longer be found. One was suffering from alcoholic pneumonia and cirrhosis of the liver, and the other from influenzal pneumonia.

In addition, I have observed 15 cases of primary disease of the hæmopoietic organs—namely, lymphatic leukæmia 6, "pernicious" anæmia 3, secondary carcinoma of the bone-marrow 2, myeloid leukæmia 2, Banti's disease 2, in all of which death took place, and lymphoidocytes were present in the circulating blood. The proportion of lymphoidocytes in the films varied in the first series from 3 to 11 per cent., and in the second from 5 to 20 per cent. I do not, however, suggest any correlation between these proportions and the severity of the disease, as it is by no means certain that the proportion of primitive cells of various types does not vary from time to time when they are present.

These observations show that the appearance of the primordial cell in the circulation is not confined to disease of the hæmopoietic organs, though I have been unable to find any record of their presence in man except in the leukæmias. So far as this goes, it serves, I think, to emphasise the importance of studying the histological features of the blood cells instead of merely relying on their numerical proportions as found in a mechanical count where they are classified under rigid types. It is frequently possible not only to trace in the same film gradations between the recognised mature cells and their progenitors, but also to observe a shift towards one or the other end as the patient improves or gets worse, and it is therefore probable that as our knowledge of the biology of the blood cells deepens, the opinion of the pathologist on the extent of the patient's resistance to disease in general will become of increasing service to the clinician. The value of a mechanical count with the hæmocytometer is but small, unless it be supplemented by a histological study of the cells themselves in properly stained films. For this purpose I have found Leishman's stain useful for a general survey of the film, but for the finer details Pappenheim's panoptic stain is preferable and less liable to variation. Latterly I have come across no fewer than five different samples of alleged Leishman stain which were quite useless for hæmatological work, and could not be made to give the characteristic reactions by any manipulation whatsoever.

a series of four successive daily inoculations was given, each rabbit receiving the deposit of 300 c.cm. of broth culture. A week later the serums were re-tested. The type 1 rabbits showed little improvement but the three type 2 serums now agglutinated the homologous culture in 1:10, 1:20 and 1:40 dilutions respectively. Then immunisation was continued with living culture, and at the end of a further six weeks the serums were re-tested. Two type 2 serums agglutinated to 1:80 and 1:160 and one type 1 serum to 1:160. The other three type 1 rabbits died 58, 82, and 83 days after the beginning of immunisation. They had tolerated doses consisting of the deposit of 10 to 30 c.cm. of living broth culture and up to a few days before death appeared to be in good health. In each case, however, advanced pneumococcal endocarditis of the left auriculo-ventricular valves was found. Type 1 pneumococci were recovered from the vegetations and were found to be highly virulent for mice. Serum derived from the heart blood of one of the rabbits after death protected mice against infection with the above strain. Thus the injected pneumococci set up disease in spite of the presence of protective substances in the blood.

It would not be safe to generalise from these few experiments in immunisation, because so much depends upon the idiosyncrasies of the individual rabbits; they suggest, however, the necessity of using considerable amounts of culture and the probability that more active and more permanent agglutinating serums can be prepared by the use of living culture than with culture killed by heat.

Isolation of Pneumococci.

In 88 out of the 100 cases of lobar pneumonia which I have investigated the pneumococci were isolated from sputum; in 10 they were obtained from consolidated lung, and in 2 from both lung and sputum. The specimens were generally at least 24 hours old before examination, and were often sent to the laboratory through the post. The material was inoculated intraperitoneally into a mouse, which was usually found dead or dying the next morning. Cultures were made from the heart blood on blood agar plates and into blood broth. If the blood of the mouse was found to contain bacteria in addition to pneumococci, a pure culture was made from single colonies from the plate. Where the mouse died from uncomplicated pneumococcal septicæmia the strain was carried on from the blood broth culture. After incubation at 37°C. over night, the blood broth cultures were placed in the ice-chest and were subcultured every two or three weeks, so long as the strain was required. In order to preserve the strain without loss of virulence, the mouse's spleen was removed and placed in a sealed tube after being dried in vacuo according to Heim's method.

Determination of Type.

The agglutination tests were made with the rabbit serums prepared, as described above, from the standard strains of types 1, 2, and 3. For the purpose of rapid identification of type the American method was followed, with a slight modification.

The peritoneal cavity of the mouse which had died after inoculation with sputum, &c., was washed out with about 5 c.cm. of salt solution. The washings were centrifuged at a low speed to throw down the fibrin and cells. The supernatant fluid was mixed with an equal quantity of a 1 in 10 dilution of each of the three type serums. This differs from the American procedure, in which either the pneumococci from the washings are re-suspended in salt solution and used for an agglutination test, or the perfectly clear supernatant fluid is used for a precipitin test. The modification, which was adopted on account of the lack of a sufficiently high centrifugal speed, appears to be quite satisfactory. If the pneumococcus belonged to one of the three types a reaction occurred almost immediately. The fluid became more turbid and clumps rapidly formed, the process being hastened by incubation. The readings were taken after the lapse of an hour only, as often a precipitate of fibrin occurred in all the tubes after more prolonged incubation. In the case of a type 3 infection the peritoneal washings were generally mucinous, but this condition was also found on a single occasion in both a type 1 and a type 2 infection.

The result of the test of the peritoneal washings has always been confirmed by an agglutination test with a whole broth culture of the strain. Where the reaction was negative with all three serums after repeated tests and the culture was bile-soluble, the strain was classed provisionally as belonging to the American type 4 pneumococcus—i.e., the heterogeneous collection of strains not conforming to any of the three "fixed" types.

Incidence of the Types.

As a result of the tests described above, my classification of the pneumococci obtained from an unselected series of 100 consecutive cases of lobar pneumonia is as follows:—

Type	1	2	3	4
No. of cases ..	24	35	10	31

Discussion of Results.

For the purpose of comparison with the above classification, the following table gives the American results. It is taken from the monograph of the Rockefeller Institute, 1917, and shows the percentage occurrence of the various types of pneumococcus in 454 cases of lobar pneumonia.

Pneumococcus type.	Incidence.	Pneumococcus type.	Incidence.
1	33·3	3	13·0
2	29·3	4	20·3
2 (atypical)* ..	4·2		

* The incidence of atypical type 2 pneumococci has been determined only during the last two years.

In the American series types 1 and 2 taken together account for 62·6 per cent. of the cases; in the English series which forms the subject of this report the corresponding percentage is 59. The incidence of cases of lobar pneumonia attributable to type 4 pneumococci appears to be higher in this country than in America. One has to consider the possibility, since the great majority of the specimens consisted of sputum, that some of the strains isolated may be accidental oral contaminations and not the organism to which the pneumonia was due. This is most likely to be the case where type 4 pneumococci have been obtained, since this type has been shown to be a common inhabitant of the normal mouth. At the same time I do not regard this as a probable event, as the sputum was not cultured directly but was inoculated into mice. The pneumococci obtained after passage through this animal may reasonably be considered the most important as regards virulence and predominance in the sputum.

Specificity of the Types.

The following is my experience as regards the validity of the American classification. The two serological groups of pneumococci which have been designated types 1 and 2 respectively by the American observers are equally well defined. Type 3 differs from the first two not only serologically, but generally shows also distinctive morphological and cultural characteristics. The simple agglutination test is sufficient for identification of each of these three types and it is unnecessary to apply the method of absorption of agglutinins. I have not done many experiments to determine whether this latter method would reveal individual differences between members of the same group. In an absorption experiment made with five type 2 strains upon types 1 and 2 serums, the type 2 serum was exhausted of agglutinins and the type 1 serum remained unaffected.

The unclassified strains in my series, designated type 4, did not react with any of the three type serums, 1, 2, and 3, in a dilution of 1:20. This group of strains contains many types, as Olmstead[2] has shown. Six types, including the American atypical types 2 A and 2 B, have so far been defined in the present investigation, but the classification has not been completed.

It is quite clear that there are three main antigenic components in the pneumococcus group; these three components appear to exist in a relatively pure condition in the three standard American types of the Rockefeller Institute. It is possible that if serums from unselected strains are used cross-agglutination between the three chief types and their respective serums may occur. Agglutinating serums prepared from horses appear to be less selective than rabbit serums.

---

[2] Journ. Immunology, ii., p. 125, 1917.

A Text-book of General Pathology.

Second edition. By J. Martin Beattie, M.A. N.Z., M.D. Edin., M.R.C.S., L.R.C.P. Lond., and W. E. Carnegie Dickson, M.D., B.Sc., F.R.C.P. Edin. London: William Heinemann. 1921. Pp. 496 + xlv. 31*s.* 6*d.*

The second edition of this text-book has been carefully revised and considerably enlarged, both in the size and the number of the pages, and fresh chapters have been added on the granulomata and on fever. The features which assured success on first appearance have been preserved, and the additions can only enhance the popularity. The early chapters on the cell in health and disease and the degenerations are well done, though the section on jaundice is scarcely worthy of the rest. The section on the disturbances of the circulation is equally satisfactory, and the discussion on the pathology of infarction is particularly good. The chapters on inflammation and repair are original and up to date, and are enriched by some fine plates and figures from a thesis by Dr. J. W. Dawson. The treatment of neoplasms, though not inspiring, is adequate, and the chapter on animal parasites is unusually elaborate.

So far we have nothing but praise for an excellent text-book, but we must enter a word of protest against the illustrations. The numerous coloured plates are beautiful, and the drawings from Dr. Dawson's thesis leave nothing to be desired, but of the rest of the couple of hundred illustrations it may be said that they are immeasurably inferior to the text; they serve to point the moral that photographs can never be anything but sorry substitutes for skilled drawings. And though the liberal use of varied type may be appreciated by the student reading for examinations, for others it has a stop-press suggestion which is distinctly irritating.

Electro-Therapeutics for Practitioners.

Second edition. By Francis Howard Humphris, M.D. Brux., F.R.C.P. Edin. London: Henry Frowde and Hodder and Stoughton. 1921. Pp. 300. 21*s.*

The second edition of this work has been considerably enlarged. Four new chapters have been added, which deal with the uses of electricity in the treatment of diseases of the nervous system and the organs of special sense; a chapter is devoted to the galvanic, faradic, and sinusoidal currents, and another to radio-therapy. The other chapters have been enlarged to a greater or less extent. The chapter in the first edition dealing with Incandescent Light now includes an account of the Tungsten Arc Ultra-Violet Light and its indications. The uses of electricity for the treatment of diseases of the genito-urinary system are described in the chapter on enlargement of the prostate. The plan of the book has not been altered; it is a series of essays on some of the uses of electricity in medicine, describing the various methods which the author employs and the results which he has obtained.

Workers in electro-therapeutics will find much of interest in the work. The use of the high candle-power lamp for hastening recovery in cases of disease of the antrum and accessory sinuses after drainage has been established is a very practical piece of information; common colds, can, according to Dr. Humphris, often be aborted by the same treatment. Those who are in charge of the electrical departments of large hospitals and have to treat the chronic obstinate cases which have resisted the efforts of other departments are not likely to obtain so much success as is claimed for electrical measures by the author of this book; and after all, it is by the results obtained in cases that resist simple methods of treatment that the powers of electricity must be judged, especially when elaborate and costly apparatus is required. There is, however, not the least doubt that electrical treatment can procure results in the treatment of the kinds of case above mentioned when other methods cannot, and Dr. Humphris's work provides a useful guide to the maladies for which this treatment should be applied, particularly those, such as dermatological and gynæcological cases, which are seldom sent to the electrical department. The author, who was formerly President of the American Electro-Therapeutic Association, makes frequent reference to the work of American specialists. The book concludes with a useful appendix on the melted paraffin wax bath, and a glossary of electrical and electro-medical terms.

The Stomach and Abdomen from the Physician's Standpoint.

By William Russell, M.D., LL.D., ex-President Royal College of Physicians, Edinburgh; Professor-Emeritus of Clinical Medicine, Edinburgh University. London: Baillière, Tindall and Cox. 1921. Pp. 329. 15*s.*

The chief value of this book lies in the clinical descriptions of cases, 99 of which are included, giving a series of clear pictures of many of the more important diseases of the abdominal viscera. Dr. Russell is able to select from a wide experience, and his survey of the evolution of clinical teaching on such subjects as appendicitis should be of great interest to the present-day student. In the early portion of his book, which deals with gastric disorders, no mention is made of the recent developments in clinical methods for the examination of gastric secretion, though a closer acquaintance with such methods cannot but modify to an appreciable degree our views on the disorders of the chemical functions of the stomach. In particular Dr. Russell leaves uncertain what figures he takes as an index of hypochlorhydria, while his teaching that this condition is associated with delay in gastric emptying is contrary to the views of the majority of modern gastro-enterologists.

We have found no references in this book to such important subjects as nephritis, pancreatitis, or colitis; on the other hand, the author devotes whole chapters to the Cirrhoses of the Liver, Diseases of the Œsophagus, and Coli Infections of the Urinary Tract. A series of instructive X ray photographs illustrates the volume.

Diagnostic and Therapeutic Technic.

Third edition. By Albert S. Morrow, A.B., M.D., F.A.C.S. London and Philadelphia: W. B. Saunders Company. 1921. Pp. 894. 40*s.*

In this volume are set forth detailed descriptions of many of the various diagnostic and therapeutic procedures which often receive only cursory reference in general text-books. The fact that a third edition has been called for is sufficient proof of its appreciation by the profession, and there can be no question that such a book must be of service to members of any branch of medical practice. The author is eclectic in his choice of methods, fair in his judgments, and clear in his descriptions. There is an excellent and concise account of all possible methods of anæsthesia, whilst transfusion of blood is adequately described and illustrated. The Carrel-Dakin method of disinfection of wounds is given a chapter to itself. The latter part of the book deals with the technique of examination of the various regions of the body.

Though most of the information and teaching can be relied on some of Dr. Morrow's statements will not find general acceptance. Thus on p. 80 he writes: "For strangulated hernia of any variety local anæsthesia should always be the choice." Most surgeons would not assent to this statement.

There are some surprising omissions. We can find no mention of Janet's method of irrigation for gonorrhœa, and in describing the urethroscope no reference is made to the inflation of the urethra by air. The term sigmoidoscope is not found in the book, and the long form of proctoscope described is of a more clumsy pattern than many sigmoidoscopes in common use. The illustrations—nearly 900 in number—serve well to indicate the methods described, but it seems unnecessary to insert 12 illustrations cause of azoöspermia is of less importance on account of its tendency to be unilateral, to involve the testis rather than the epididymis, and to clear up with treatment.

The examination of the genital tract should include a posterior urethroscopy in order that the opening of the ejaculatory ducts may be inspected. If there is any doubt about their patency methylene-blue may be injected into the vas on each side and its passage into the urethra observed. Should no signs of obstruction be detected the absence of spermatozoa in the semen probably indicates lack of spermatogenesis. To confirm this the testis may be punctured with a hypodermic needle and a search made for spermatozoa in the fluid drawn off. The operation is a painful one and a fine needle should be employed. If repeated examinations of the testicular fluid fail to reveal the presence of spermatozoa, aspermatogenesis must be diagnosed. This occurs when the tubules have atrophied as the result of a severe orchitis—e.g., mumps. It is also found, as shown by Mott, in association with various mental conditions, in some cases of cryptorchism, in advanced malignant disease anywhere in the body, and occasionally in chronic alcoholism. Old age, although productive of oligospermia, is not as a rule a cause of aspermatogenesis. I have examined the testes of a large number of old men dying of prostatic enlargement or its sequelæ and have been surprised how rarely spermatogenesis entirely fails, even in senile cases.

Necrospermia and Oligonecrospermia.

A certain degree of oligospermia is usually associated with the necrospermia, as is also the appearance of abnormal types of spermatozoa. Amongst these are large-headed and small-headed forms, spermatozoa without heads or double-headed monsters. The condition is generally associated with inflammation in the genital tract, and pus cells are discovered in the semen. Statements to the effect that spermatozoa become motionless in the presence of pus or blood are erroneous; but as inflammation is often accompanied by an acidity of the secretions pus is inimical to the activity of the spermatozoa. Necrospermia calls for careful examination of the genital tract for signs of prostatitis and vesiculitis. The appearance of an excess of crystals and amyloid bodies in the semen is not uncommon in this condition. Of the exact significance of this I am doubtful.

The Accessory Sexual Glands.

The rôle of the accessory glands, and notably that of the prostate and vesicles, is unknown. G. Walker showed that excision of both prostate and vesicles rendered rats sterile, whereas their breeding power was apparently unaltered by removal of only one of the glands. Ivanoff succeeded, however, in impregnating rodents by means of spermatozoa drawn directly from the testes. But even although the secretions of the prostate and vesicles may not be essential to fertility they are undoubtedly of considerable importance.

It is probable that there is some overlapping in the function of the two glands, as their degree of development is subject to enormous variations throughout the animal kingdom, absence of the one gland being compensated for by a considerable degree of development of the other. Although in man the prostate and vesicles may appear very different in structure, in other animals, notably the rhinoceros, the vesicles and prostate are so similar in appearance that it is difficult to say where one ends and the other begins. Whatever may be their exact function it is certain that the accessory glands have a very considerable bearing on fertility, and that their secretions, as well as adding bulk to the semen, provide a fluid favourable to the survival of the spermatozoa subsequent to emission. For this reason the condition of the prostate and vesicles should be carefully investigated in any potential case of sterility. Further investigations will be required before the true significance of the accessory vesical glands is understood.

Prognosis and Treatment.

As a result of a conscientious examination it is possible to arrive at a much more precise prognosis in the case of the male than is possible with the female; for whereas nature plays the chief rôle in producing sterility amongst women, disease is the chief factor amongst men. The fertility of a man can, indeed, be expressed as a percentage according to the number of active well-formed spermatozoa found in the semen, and the case returned as 80 per cent., 60 per cent., 50 per cent., &c., efficient. If this system be adopted it will soon become apparent to the observer how many husbands show a diminished number of healthy spermatozoa in the semen, or else give evidence of chronic inflammatory lesions of the genital tract, and consequently, although not absolutely sterile, are relatively so.

In a series of 87 childless marriages in which the wife had been declared normal, Wolbarst found the following incidence of trouble amongst the husbands: 57 per cent. suffered from azoöspermia, 35 per cent. from oligonecrospermia, and 13·5 per cent. from oligospermia. It must also be borne in mind that the mere fact that a normal number of healthy spermatozoa have been found in the semen, and that these retain their mobility for several hours after emission, affords no guarantee that the same mobility will be retained when the semen becomes mixed with the female secretions. To determine this specimens must be taken from the cervix or fundus uteri three or four hours after coitus and examined according to the method advocated by Hühner. As, however, such interesting questions as the action of the female secretions on the spermatozoa and the possibility of agglutination and incompatibility, &c., belong to the subject of female sterility they will not be discussed here. Suffice it to say that the well-known hostility of the vaginal secretion to the life of the spermatozoa appears to be the result of its bacteriological content rather than of its acid reaction.

The treatment of sterility in the male will depend on the category in which the case has been placed. An azoöspermia due to the occlusion of the ejaculatory ducts is generally associated with a chronic prostatitis for which the appropriate therapeutic measures must be adopted, including, if necessary, catheterisation of the ducts through a posterior urethroscope. The latter may be a simple or an extremely difficult, if not impossible, operation, the determining factor being the situation of the openings. If the obstruction is the result of bilateral epididymitis the operation of vaso-epididymostomy, devised by Martin and modified by Lespinasse, may be undertaken, provided that the existence of spermatogenesis has been proved by means of direct puncture of the testes. For the condition of oligo- or necrospermia due to vesiculitis a prolonged course of massage and dilatation must be carried out.

When spermatogenesis is defective or lacking, treatment is of less avail. Attention may be paid to the habits, mode of life, and general health of the patient, and a course of orchitic or lymphatic gland extract given in the hopes of exerting an influence on the defective action of the testis. Occasionally aspermatogenesis will be found in men who otherwise appear to be perfectly normal.

Although at the present moment it may be impossible to find an explanation for such a puzzling condition of affairs, it is not unlikely that the key to the riddle will be provided by an increased knowledge of the relationship of the testes to the endocrine glands. But as yet little is known of the influence exerted on the testis by the hierarchy of the ductless glands, and the suggestion that certain cases of aspermatogenesis may be explained in terms of endocrinology must be regarded as purely speculative. Whether the suggestion be right or wrong there can be little doubt that if progress is to be made in the treatment of sterility less attention must be paid to the anatomy of reproduction and more to its physiology.

Public Health Services.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County of Norfolk.

Dr. J. T. C. Nash has recently issued his annual report which is chiefly a record for the year 1919, but also embraces features common to 1920. The population of the administrative County of Norfolk at the last Census (1911) was 321,733; the birth-rate for 1919 on the estimated population was 17·3, and the death-rate 14·3. The death-rates of pregnant and parturient women were somewhat in excess in Norfolk during a series of years as compared with England and Wales as a whole, except in the years 1916 and 1917, when they were lower. Dr. Nash considers that this was due in part to the following factors: (1) lack of a sufficient number of qualified midwives; (2) lack of special hospital provision for difficult cases in scattered and sparsely populated villages; (3) inadequacy of some cottages for even a normal confinement; and (4) deficient nutrition of pregnant women.

To deal with the first three factors Dr. Nash suggests that the county council should make arrangements with available hospitals or hostels for the reception of cases for which adequate provision at home is impossible, and should circularise midwives and practitioners as to such provision. One cannot help thinking that if the stigma of the Poor-law was removed, ample accommodation for such cases could be secured in the numerous Poor-law infirmaries in the county, where there is usually a qualified midwife in charge, whose maternity duties are almost entirely restricted to attending at illegitimate births. The fourth factor is largely met now by the Administration of the Milk (Mothers and Children) Order, 1919. The fact that maternal mortality was lower in 1916 and 1917, when income was better and rationing of food was in force, enabling all, even the labouring class, to get a proper share, is suggestive that deficient nutrition is an important factor.

During a series of five years the average infantile mortality for the 12 urban districts (all under 6000 population, except King's Lynn, 20,205) was 90·4, and for the 20 rural districts 81·6. Total average for the county 83·2. These figures, though lower than those of England and Wales as a whole, are too high for a rural area, seeing that the England and Wales figures include all the large towns with conditions which favour a high diarrhœa mortality in years favourable to fly-life and germ-life. Dr. Nash considers that the chief causes of infantile mortality in Norfolk are prematurity and immaturity, which indicates that special attention should be given to ante-natal conditions, especially to the proper nutrition of pregnant women. He lays particular stress upon oral sepsis, associated with carious teeth and anæmia, as conditions inimical to the nutrition of the unborn fœtus, and is convinced that efficient dentistry would be a factor of great value in reducing the death-rate from prematurity. Traditional fallacies as to the feeding of infants are also responsible for a certain number of infant deaths, but recent researches as to the value of the vitamins in food should tend to lessen so-called "deficiency diseases." In 1919 the Norfolk County Council employed three whole-time health visitors, in addition to Miss Fowler (inspector of midwives and supervising county health visitor); 62 midwives and nurses of the Norfolk Nursing Federation were also employed, when possible, as part-time health visitors, at a fixed sum per child visited. During the year 1937 infants under one were followed up by health visitors, out of 4365 live births notified; that is, less than half the number of infants were visited. Dr. Nash advises the appointment of three more whole-time health visitors, to ensure that nearly the notified births, at least, should be followed up every three or four months. Several infant welfare clinics have been established throughout the county, in both rural and urban districts. In this connexion Dr. H. H. Back, medical officer of health for Aylsham and Blofield Districts, reports: "Doubts have often been expressed as to whether infant welfare clinics could be carried on with advantage in a rural district. The undoubted success of the Blofield clinic will go far to show that under efficient management they can be of great value both directly to those attending them and indirectly through their educational influence."

With reference to infectious diseases, three cases of a mild and unusual type of small-pox occurred in the Loddon Rural District; they were part of an outbreak which more seriously affected the neighbouring districts of East Suffolk; no deaths occurred in Norfolk. Of scarlet fever, 896 cases were notified in the county, with 17 deaths, giving a case-rate mortality of 1·9 per cent., the zymotic death-rate for the county being 0·057. Diphtheria was also in excess; 462 cases were notified, with 47 deaths—a case-rate mortality of 10·17, and a zymotic death-rate of 0·15. Of enteric fever 35 cases were notified, with four deaths, a case-mortality of 11·49 per cent. This comparatively low figure is to be accounted for by the fact that a considerable number of the cases notified were of the "paratyphoid" variety.

There were only five deaths in Norfolk attributable to measles in 1919. This disease has ceased to be notifiable, and Dr. Nash considers that the method of notification through the schools, which has been in vogue in Norfolk since 1908, is much more effective, and still more so is the recent provision of the Ministry of Health of grants in aid of the salaries of health visitors for home visiting and home nursing of cases of measles, and for the provision of hospital or convalescent beds for cases of measles occurring in children under 5 years of age. Whooping-cough accounted for the deaths of 45 children under 5 in 1919. There were 255 deaths from influenza, against 749 deaths in 1918, besides a large increase in deaths from bronchitis, pneumonia, and pulmonary tuberculosis, many of which were, no doubt, attributable to the influenza epidemic of that year. There were four notifications of encephalitis lethargica disease in 1919, one of which was not confirmed in hospital. Dr. Nash states that he ranks himself with Dr. W. H. Hamer and Dr. F. H. Crookshank, of London, in supporting the view that the syndrome encephalitis lethargica is but a manifestation of the protean epidemic disease called influenza, though the more commonly accepted view is that it is a well-defined disease.

With regard to the isolation of infectious diseases the county of Norfolk is at a great disadvantage, from the fact that it possesses no county isolation hospital, a fact which Dr. Nash reported on to the Public Health Committee in December, 1917.

In July, 1919, the County Public Health Committee reported that they had received an offer of a site near East Dereham, which is a very central situation, for the purposes of a county isolation hospital. It was later decided to purchase the site as from October, 1921, so that it is to be hoped that Norfolk will not much longer have to bear the reproach of a lack of accommodation for infectious diseases.

A considerable section of Dr. Nash's report deals with tuberculosis. A comprehensive scheme has now been adopted by the Public Health Committee, which includes as a commencement: (1) The appointment of a tuberculosis officer and resident nurses in defined areas, acting under the supervision of the county medical officer of health; (2) contracts with existing institutions in the county for beds for cases needing institutional treatment; (3) suitable cases, after institutional treatment, to be transferred to the farm colony. The scheme was approved by the Ministry of Health, and Dr. W. B. Christopherson was appointed tuberculosis officer for the county and began duty on August 7th, 1920. A tuberculosis dis-

Reviews and Notices of Books.

MEDICAL ANNUAL, 1921.

Bristol: John Wright and Co.; London: Simpkin, Marshall, Hamilton, Kent and Co. Pp. 616. 20s.

THIS volume, the thirty-ninth of the series, embodies a summary of the published records of progress in surgery and medicine during the past year by a number of distinguished authors. The reviews under each heading are clear, supported by full references to original papers, and the amount of space allotted to each disease is well proportioned. Amongst articles of special interest may be mentioned that on encephalitis lethargica. We are glad to note that autoserum therapy has been practised in this disease—the experimental results obtained with rhesus monkeys in the homologous condition polio-encephalitis afford strong indications as to its probable value. The treatment of ankylostomiasis by oil of chenopodium administered by duodenal tube is advocated and the results as regards the anæmia are apparently highly encouraging. Recent work on deficiency diseases is reviewed and consideration of the subject is brought up to date. An excellent summary of work on the kidney is included under the heading nephritis; Dr. Mackenzie Wallis's recent observations on functional albuminuria are discussed and reference is made to Barach's work on the relation of albuminuria to prolonged violent muscular exertion. The differences between chronic parenchymatous and chronic interstitial nephritis are indicated, and the dietetic treatment appropriate to each variety of the disease is fully described.

The cognate problems of the chemistry of the blood are succinctly reviewed by Dr. O. C. Gruner. His article on the cytology of the blood, beautifully illustrated by original coloured plates, presents a theory so novel in its conception and apparently subversive of our most cherished ideas, not only on the origin of blood cells but on the whole subject of body metabolism and the part played by enzymes in vital processes, as to read like a fairy tale. We regret that he could not even outline the experimental results on which his far-reaching generalisations are based, but his message is fascinating and suggestive, and many will doubtless avail themselves of the extensive bibliography on which he has based his sketch to follow up the subject for themselves. On the surgical side, Dr. Robert Hutchison reviews the latest medical and surgical treatment of gastric and duodenal ulcer. The relationship of ulcer to carcinoma is dealt with in an article on the surgery of the stomach. An article on the surgery of the thorax emphasises the satisfactory progress which has been made in the treatment of empyema, bronchiectasis, and abscess of the lung; perhaps a larger section might have been devoted to the newer aspects of this important branch of surgery. A special section on orthopædic surgery from an American source is devoted to a review of all that is most recent in a branch of work which is highly progressive, both in this country and abroad.

The book is attractively produced, clearly printed, and provided with a useful index, supplemented by ample cross-references under corresponding headings in the text.

DISEASES OF THE EAR, NOSE, AND THROAT.

Intrinsic Cancer of the Larynx and the Operation of Laryngo-Fissure. By IRWIN MOORE, M.B., C.M. Edin., Surgeon to the Hospital for Diseases of the Throat, Golden-square. London: Hodder and Stoughton. 1921. (University of London Press.) Pp. 147. 20s.

MR. Irwin Moore seems to have read nearly everything that has been written on his subject, and has produced a monograph which is crammed with references; indeed, one might almost complain that the author lays so much stress on the work of others and so little on the results of his own clinical experience. He devotes comparatively little space to the clinical aspects and diagnosis of the disease, and he makes no mention of that form of senile tuberculous infiltration of the vocal cord which is so readily mistaken for epithelioma. But he rightly emphasises the fact, which cannot be too widely made known, that the majority of cases of intralaryngeal cancer remain undiagnosed until the disease has advanced too far for removal by the relatively safe and simple operation of laryngo-fissure. Not sufficient notice is taken of the early symptom of hoarseness; everyone in whom hoarseness persists for more than a few weeks should have the vocal cords thoroughly inspected. More than half the book is occupied by a careful account of the technique of the operation of thyrotomy, or laryngo-fissure, and this section is beautifully illustrated and full of valuable detail, including descriptions of several instruments designed by the author.

This monograph cannot fail to be most useful to any surgeon about to perform the operation of laryngo-fissure.

Diseases of the Ear, Nose, and Throat in Childhood. By DOUGLAS GUTHRIE, M.D., F.R.C.S., Surgeon to the Ear and Throat Department, Royal Hospital for Sick Children, Edinburgh. London: A. and C. Black. 1921. Pp. 88. 5s.

THIS is a very short epitome of diseases of the ear, nose, and throat as they affect children, and is too brief to be of great practical value. Some diseases, very rare in children, such as nasal polypus and Vincent's angina, receive mention, while only four lines are devoted to retropharyngeal abscess, which is an important affection of infancy. The volume is not likely to be useful to medical men, as they are already possessed of the elementary knowledge it contains; but it should prove helpful to nurses and child-welfare workers, and will serve a good cause if it stimulates their interest in the treatment of common and important diseases of childhood.

A Guide to Diseases of the Nose and Throat, and their Treatment. Second edition. By CHARLES A. PARKER, F.R.C.S. Edin., Consulting Surgeon to the Throat Hospital, Golden Square; and LIONEL COLLEDGE, M.B., F.R.C.S., Surgeon to the Ear and Throat Department, St. George's Hospital. London: Edward Arnold. 1921. Pp. 583. 25s.

THIS text-book, intended especially for post-graduate students, has been considerably altered and in parts entirely re-written. The work suffers somewhat from a lack of orderly arrangement. A few operations on the larynx and trachea are described in the preliminary section under general methods, while others are discussed under the headings of the affections for which they are designed. Thus, thyrotomy is found on p. 74 and Lack's modification thereof on p. 547; laryngostomy for stenosis is mentioned on p. 76, while other methods of treating this disease are described under syphilis on p. 139 and under perichondritis on p. 482; but laryngeal stenosis is nowhere discussed as a separate entity. The second section deals with the complications of general diseases, including tubercle and syphilis; such difficult subjects as the diagnosis of tuberculous laryngitis have therefore to be discussed before the student has reached an account of simple laryngitis, and the action of nervous diseases in producing paralyses of the vocal cords is considered early in the book, while the paralyses themselves are described in the end. In spite of these comparatively minor defects, the book is a most useful one; of medium size, it contains a great quantity of accurate information, is eminently sane and free from fads, and has been brought thoroughly up to date. A notable feature is the completeness of the description of such affections as usually receive but scant attention in text-books. The book should prove of great value to post-graduate students and practitioners.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JUNE, 1921.

(*Specially compiled for* THE LANCET.)

Cities and Boroughs.	Estimated civil population, 1920.	Notified Cases of Infectious Disease.												Deaths from Principal Infectious Diseases.									Deaths from all causes.	Death-rate per 1000 living.
		Enteric fever.	Other continued fevers.	Small-pox.	Scarlet fever.	Diphtheria.*	Erysipelas.	Poliomyelitis and polioencephalitis.	Encephalitis lethargica.	Cerebro-spinal fever.	Puerperal fever.	Total.	Annual rate per 1000 persons living.	Enteric fever.	Small-pox.	Measles.	Scarlet fever.	Whooping-cough.	Diphtheria.*	Diarrhœa and enteritis (under 2 years).	Total.	Annual rate per 1000 persons living.

* Including membranous croup.

Kensington, Chelsea, the City of Westminster, Hampstead, Wandsworth, and Camberwell; and the highest in Hammersmith, Hackney, the City of London, Shoreditch, Greenwich, and Woolwich. The prevalence of enteric fever was somewhat greater than in the preceding month; of the 36 cases notified during the five weeks ended July 2nd 3 cases belonged to each of the boroughs of Kensington, St. Marylebone, St. Pancras, Stepney, Wandsworth, and Camberwell. There were 23 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 10, 10, and 18, at the end of the three preceding months; the weekly admissions averaged 4, against 3, 2, and 5 in the three preceding months. The prevalence of scarlet fever was about equal to that in the preceding month; this disease was proportionally most prevalent in Hammersmith, the City of London, Shoreditch, Stepney, Bermondsey, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 3621 scarlet fever patients at the end of the month, against 3187, 3217, and 3375 at the end of the three preceding months; the weekly admissions averaged 506, against 469, 441, and 507 in the three preceding months. The prevalence of diphtheria was also about equal to that in May; the greatest proportional prevalence of this disease was recorded in Hackney, Holborn, Finsbury, the City of London, Shoreditch, and Bethnal Green, a group of adjoining areas. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 2652, 2429, and 2121 at the end of the three preceding months, further fell to 1896 at the end of June; the weekly admissions averaged 235, against 290, 261, and 241 in the three preceding months. Erysipelas was proportionally most prevalent in Paddington, St. Marylebone, Holborn, Shoreditch, Southwark, Battersea, Deptford, and Greenwich. Ten cases of encephalitis lethargica were notified during the month, against 77, 56, 24, 14, and 18 in the five preceding months; of these, 2 belonged to Lambeth and 2 to Wandsworth. The notified cases of cerebro-spinal fever numbered 5, against 14, 12, and 11 in the three preceding months; of these, 2 belonged to Islington. Nineteen cases of puerperal fever were notified during the month, against 33, 30, and 32 in the three preceding months. The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ended July 2nd the deaths of 4082 London residents were registered, equal to an annual rate of 9·4 per 1000; in the three preceding months the rates had been 13·6, 12·6, and 11·2 per 1000. The death-rates ranged from 6·5 in Paddington, 7·3 in Chelsea, 7·9 in the City of London and in Woolwich, 8·3 in Hampstead, and 8·5 in Greenwich, to 10·7 in Kensington, 11·2 in St. Marylebone, 12·0 in Finsbury and in Southwark, and 12·6 in Holborn. The 4082 deaths from all causes included 209, which were referred to the principal infectious diseases; of these 6 resulted from enteric fever, 18 from measles, 33 from scarlet fever, 37 from whooping-cough, 63 from diphtheria, and 52 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded in Stoke Newington or in the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Chelsea, St. Marylebone, Hampstead, Bermondsey, Greenwich, Lewisham, and Woolwich; and the highest in Hammersmith, Holborn, Finsbury, Poplar, and Battersea. The 6 fatal cases of enteric fever were one fewer than the average in the corresponding period of the five preceding years. The 18 deaths from measles were less than one-sixth of the average; of these, 6 belonged to Stepney, 2 to Islington, 2 to Lambeth, and 2 to Camberwell. The 33 fatal cases of scarlet fever exceeded the average by 25; of these, 6 belonged to Poplar, 3 to Hammersmith, and 3 to Wandsworth. The 37 deaths from whooping-cough showed a decline of 27 from the average; of these, 6 belonged to St. Pancras, 4 to Southwark, and 3 to Islington. The 63 fatal cases of diphtheria were 16 in excess of the average; the greatest proportional mortality from this disease occurred in Fulham, Finsbury, Battersea, and Camberwell. The 52 deaths from infantile diarrhœa were 9 below the average; of these, 6 belonged to Battersea, and 4 to each of the boroughs of Paddington, Islington, and Southwark. In conclusion, it may be stated that the aggregate mortality in London during June from these principal infectious diseases was 31·7 per cent. below the average in the corresponding period of the five preceding years.

showing how to pass a urethral sound. In Fig. 298 the line of the lung in relation to the ribs is inaccurate. The style of writing is easy and clear, though split infinitives have no terrors for Dr. Morrow, and his words are occasionally ill-chosen.

The book deserves to be in the library of every practitioner.

PRIESTLEY IN AMERICA, 1794-1804.

By EDGAR F. SMITH. Philadelphia: P. Blakiston's Son and Co. 1920. Pp. 173. $1.50.

THE average Englishman's knowledge of Priestley consists in the impression that he was an unpopular and heretical Radical who discovered oxygen and whose house was burned down by a mob. These facts are true, but few know that Priestley was also a learned natural philosopher, a man of letters, and a citizen of the French Republic, to which last circumstance the burning of his house in 1791 was due. He left Birmingham and was for a short time in charge of a chapel at Hackney, but finding that his opinions rendered life in England unendurable removed to America in 1794. It is at this date that Mr. Smith's little book begins, and he has produced a very readable account of Priestley's life in America by collecting various incidents reported in contemporary newspapers and books. No doubt Priestley was glad to arrive in a land which was Republican in government and where religious liberty existed in theory, if not, as is apparent here and there from Mr. Smith's extracts, altogether in fact; but our sympathy goes out to him on account of the numerous addresses of welcome to which he had to listen and respond. He was invited to the post of Professor of Chemistry at Philadelphia, but he declined to accept it. For some reason or other Philadelphia did not appeal to him, a dislike which was shared by John Adams, second President of the United States, for, as Priestley says in a delightful letter, "John Adams, when he first came down to Philadelphia fresh from Boston, stood aghast at this life into which he was suddenly thrown and thought it must be sin. But he rose to the occasion, and after describing in his diary some of the 'mighty feasts' and 'sinful feasts,' says he drank Madeira 'at a great rate and found no inconvenience.'" Priestley, however, does not seem to have conquered his aversion, for he remained at Northumberland, Pennsylvania, where he had a house and where he died in 1804.

We congratulate Mr. Smith, who we gather from his preface is a chemist, upon a very interesting little book, although we wish that he had given the references for the various excerpts which he has quoted.

JOURNALS.

School Hygiene. No. 2, Vol. XII. London: Adlard and Son. 1*s.* 6*d.*—It is gratifying to note the revival of this journal. The present number contains some interesting material, including a full report of the Conference of Educationists on Punishment in Schools. The Conference supported the resolution of the Medical Officers of Schools Association deprecating caning on the hand, which seems to be confined entirely to the public elementary schools. There are two interesting papers from the Edinburgh Conference of Scottish Medical Officers of Schools. Dr. A. MacGillivray, in his survey of the educationally blind child, favours full correction of myopes, and is of the comforting opinion that the vision of the race has probably not deteriorated at all in the last 7000 years. The skin diseases of school children have been very thoroughly investigated and treated in Edinburgh, and Dr. Norman Walker gives his experience of the last dozen years, adding some observations on the general medical outlook. Dr. C. J. Thomas, who has had more experience than anyone in this direction, draws attention to many points in connexion with the employment of children in theatres. An article on the public health aspect of physical exercises, by Dr. James Kerr, shows how the Ling system, while still necessary, has failed in popular attraction. He asks for a system having emotional content, and having regard to the herd instinct innate in man, wishes to socialise exercise so as to make it desirable and desired throughout life. Dr. Octavia Lewin describes the work of her "nasal hygiene" clinic, and several reviews conclude the 66 pages of this excellent journal.

King's College Hospital Gazette. June, 1921. Vol. I., No. 1.—This is the first number of the Gazette to be published since the war. It will now be issued quarterly at one shilling. In a foreword the editor traces the development of the hospital and medical school since their removal to Denmark Hill in 1913, and more especially since peace was declared. To the first number a historical and critical review of encephalitis lethargica is communicated by Dr. S. A. Kinnier Wilson; Dr. A. C. D. Firth gives a short account of Ambroise Paré as surgeon, and there are several other prose and verse contributions of a literary nature, some serious and others humorous. The present intention of the Editorial Committee responsible for the publication of the Gazette is that it shall contain clinical articles of practical value to students and practitioners, together with literary matter, reviews, and articles dealing with the social life and athletic activities of the hospital.

The Fight Against Disease.—This publication of the Research Defence Society is the quarterly report of the Society's activities, which during the years from 1913 to 1920 was issued only to members and associates, but is now sent to the chief public libraries and may be obtained from any bookseller or agent. A summary is given of Sir John Rose Bradford's address on "The Place of Experiment in the Science and Art of Medicine," delivered at a meeting of the Oxford branch of the Research Defence Society in March; the annual report of the Lister Institute of Preventive Medicine is described in outline, and mention is made of the Dogs Bill talked out on June 3rd on the occasion of its second reading in the House of Commons. The Government report for 1919 on experiments performed on animals during that year is made the basis of a short exposition of the point of view of those who realise the necessity of animal experiments and the care taken to prevent infliction of unnecessary pain during their performance. The names are given of late presidents and vice-presidents, with the striking list of vice-presidents as it stood in 1916. It is hoped in future to publish the report six times a year.

Transactions of the American Association of Genito-Urinary Surgeons. Vol. XIII. 1920. Baltimore: Williams and Wilkins Co. Pp. 280.—In this volume are published the papers read by members of the Association at the Mayo Clinic in 1920, together with the discussions which followed them. The most important item in this publication is a communication from Dr. H. H. Young, explaining his views on the pathology of tuberculosis of the seminal tract, and giving the details of the operation which he prefers to employ for its removal. He considers that the primary focus of genital tuberculosis is in the seminal vesicles, and that from here the disease spreads to the epididymis and elsewhere. The operation which he advises he calls "excision of the tuberculous seminal tract." The vesicles are exposed from the perineum and brought into the wound by the author's prostatic tractor. The diseased vesicle, and perhaps part of the prostate, are thus removed, the vas being divided and a clamp left on its upper end. In the final stage of the operation the epididymis and all that remains of the vas belonging to it are removed through an inguinal incision, the process of removal being helped by to-and-fro traction between the operator and an assistant pulling upon the clamp left in the perineum. Fifteen cases which have been operated upon are here reported, and the results seem good; the paper is very well illustrated. Thirteen other papers are published, one of the most interesting being a description by J. W. Caulk of a method of producing local anæsthesia suitable for operations in cases of obstruction at the neck of the bladder.

being substituted for it, which entirely contradicted its essential purpose, but as sufficient notice of this amendment had not been given it could not be immediately adopted as the policy of the Association, but must be regarded as a strong expression of the opinion of the Representatives. The original recommendation was to the effect that the Association could not protect a medical man from the consequences of refusing to divulge information obtained professionally (1) in a court of law where the court has ruled that information so obtained must be divulged, (2) when it is provided by an Act of Parliament that he must do so, as in the case of notification of disease. In other words, any refusal to divulge at a trial professional confidences must be at the risk of the individual practitioner. The resolution further stated that resistance would be given by the Association to any "further encroachments" on professional secrecy. The amendment, which was moved by Dr. H. G. DAIN, recommended "that the Association use all its power to support a member who refuses to divulge, without the patient's consent, information obtained in the course of his professional duties," to which was afterwards added the sentence "except where it is already provided by Act of Parliament that he must do so." Thus as to obedience to statements to be made in accordance with a statute agreement seems to have been arrived at, subject to the observation that the nature of the encroachments to be resisted in the future is left obscure. Notifications under Acts of Parliament are a form of revelation of professionally acquired knowledge, which are usually introduced on public grounds and in the interest of preventive measures against disease. They are also frequently the result of the advice of the medical profession, or of an important section of it.

As to the main issue debated at the meeting, the giving of medical evidence without the consent of the patient concerned on the order of the judge, it will be difficult to support unreservedly and logically either the Council's original recommendation or the amendment provisionally adopted; each is of too general a character. The Council's recommendation denies support in any case of resistance to any judicial decision of the kind indicated, whatever the nature of the trial in question, and whatever may be the means by which the required information has been obtained by the medical man. The discussion was induced by a recent judicial decision to the effect that knowledge acquired in a clinic for venereal disease might be ordered to be published in a court of law. Now the fact that the particular patient had no objection to the doctor giving evidence does not affect the principle involved, for the judge could know nothing about the patient's wishes. A judge's ruling is a common factor in all cases where the witness is unwilling to testify. One way, at any rate, of meeting such a ruling is a test case. The Council's recommendation appears to be that all judges' rulings must be acquiesced in without resistance, and this we hold to be a wrong view. But Dr. DAIN's amendment may prove too sweeping to be practicable in operation, and we are strengthened rather than shaken in our opinion by some of the arguments used in its support. Dr. DAIN treated his amendment as embodying the ascertained views of the public, who would support the proposition that the doctor should never tell what his patient told him, including, we presume, such important matters of fact as he has observed for himself. He made reference especially to civil cases, but his amendment would cover both civil and criminal trials. As to this we point out that in the trial of crime a doctor's evidence withheld might conceivably lead to the escape of a criminal from the consequences of his crime, or the conviction of an innocent man for a crime which he never committed. To give examples of what the doctor's silence might involve in civil causes, it might constitute him as a silent abettor in a fraud attempted on a life assurance company, in a case of the wrongful substitution of an infant, or in the effort of a guilty husband or wife to deceive the divorce court. We do not multiply instances of the kind of trial in which the medical man may be asked to give evidence as to a patient without the patient's consent. It is enough to say that they are rare compared with the innumerable other occasions when medical evidence is sought. They are, however, often of importance when they do occur, and it is difficult to assent to the proposition that the public, or any section of it whose opinion would carry weight, would view with satisfaction the miscarriage of justice rather than see the medical profession assist in its due administration. The arguments founded on the privilege of solicitors lose sight of the fact that with the withdrawal of the privilege the administration of justice could hardly be carried on. A supposed privilege of priests was also invoked by a speaker on Dr. DAIN's amendment. We are aware of no right or power of the clergy of any denomination to refuse to give evidence when ordered to do so by the court. An account given by Dr. R. J. ROWLETTE at the meeting of the refusal of certain hospitals to give information to the military authorities in Ireland had no bearing that we can see on the question of resisting the order of a judge in the actual course of a trial. We should be the last to support any effort to convert medical men into detectives of crime. In contact with a suspected criminal a doctor may have a duty as a citizen to consider, but his wisest course will be to confine his attention to his patient's physical needs, and to divert it as far as possible from everything else concerning him. It is well not to prejudice the case for professional secrecy by overstating it, or by asking too much.

The refusal, however, of the Council of the British Medical Association to countenance or support any idea of resistance to judicial authority in any circumstances, and the amendment which advises support to all such resistance, appear alike inadequate to meet the new conditions which have arisen. These are the outcome of Mr. Justice HORRIDGE's decision as to information acquired at a venereal clinic, coupled with that of Lord MERSEY in another divorce case with regard to records in the custody of a medical officer of health. The possible use in personal litigation of medical history cards, compiled under the Insurance Act, has also to be considered. Both the Council's recommendation and that contained in the amendment appear to contemplate the possibility of test cases, undertaken with the support of the British Medical Association, or with that of the profession generally, in order to ascertain the exact position of the medical witness in certain circumstances with a view to future action. The one, however, refuses the consideration of any test case, and the other proposes to make a test case out of any refusal to give evidence. It is suggested that the better course would be to reserve a discretion to give all support possible in a case in which the principle involved might deserve the support of the profession at large, and of that section of the public whose opinion carries weight. The case of the venereal clinic is a good example of our meaning. The idea that anything passing within the walls of the clinic would be secret was promoted and fostered by the medical profession and by laymen alike on grounds pensary with laboratory and office accommodation has been provided in Norwich. The *farm colony is* now in working order. A short account of it was published in THE LANCET of May 21st, p. 1096.

Urban District of Swinton and Pendlebury.

IN many respects the report for 1920 submitted by Dr. W. *Stewart Stalker is interesting and satisfactory.* The report is valedictory and contains a short review of the districts' health during a period of transition and reform. *In 1900 the death-rate for Swinton and* Pendlebury was 20·2; to-day it is 12·4. The lives spared have amounted to over 2000. At the beginning of the century *80 infants of every 100 born survived* the first year of life; to-day the number is 90. Then, too, 90 persons per 30,000 population contracted typhoid fever *against 2 last year. At the corresponding* periods 60 and 4 persons respectively died of diarrhœa. A saving of public money has been secured which outweighs by *far* the expenditure incurred in effecting these improvements. Dr. Stalker is inclined to believe that the older methods of reducing death-rates have *nearly* attained what within their limit is an irreducible minimum. To reduce death-rates further, what must be aimed at is the pursuit of a higher standard of life on the part of the individual; this higher standard once attained, the slums, the *infant mortality, ravages of alcohol and syphilis,* and of the unhealthy industry will automatically cease to contribute to a tragic procession toward preventable death. This ideal *demands education of* the broadest type, and administering authorities possessed of vision and imagination. There are 6680 houses in the district, with *5378 water-closets, but* there still *remain 1322 privies,* and unless some scheme for rapid conversion, regardless of structural conditions, is adopted, privies *will be handed on from council to council* as a relic of barbarism; problems of economy and expediency have absolutely no claim to consideration in this connexion. *A contribution* to good legislation would be the exaction of penalties from districts which failed to furnish schemes for the conversion of all privies within a definite period.

There are some interesting and pertinent remarks on the milk question. An American Commission on Milk Standards has recommended classification of milk into three grades according to the number of contained organisms. Grade A milk may have a bacterial content which should not exceed 10,000 organisms per cubic centimetre at time of delivery to the consumer. In grade B milk the number should not exceed 1,000,000. Grade C milk, the lowest grade, is milk in which the number of organisms exceeds 1,000,000 per cubic centimetre *at the time of delivery* to the consumer. The Commission, moreover, says that whenever any community finds it necessary to allow the sale of grade C milk, *its sale should be surrounded* by safeguards such as to ensure the restriction of its use to cooking and manufacturing purposes. No sample out of 13 taken in the district of Pendlebury attained the American grade A; 7 were graded B and 6 graded C. Probably the greater portion of milk delivered in towns is grade C milk at the time of consumption. If this contention be true, then it is manifest that unattractive as is the story connected with milk supplies, there is no evidence that there are any grave pathological results. Unfortunately there is overwhelming evidence that a grade A milk inevitably and speedily becomes a grade C milk under the conditions of household storage, which obtain in this district. The vast majority of the *organisms* found in the milk are perfectly harmless, some are beneficial, and any pathogenic organisms can be rendered harmless by the simple expedient of heat sterilisation.

The staff of the School Medical Service consists of the school medical officer (Dr. Stalker), a part-time clerk, two school nurses, and an ophthalmic surgeon who attends the clinic once a fortnight and *prescribes* for cases of defective vision. The School Medical Service is still without a dentist. The need is perhaps best demonstrated in the number of young people *in the district* who are possessed of dentures. The disfigurement is apparent in a journey through the streets when the factories are releasing their operatives. *This disfigurement* will continue so long as the School Medical Service by education, prevention, and conservation fails to bring about conditions whereby the youth of the district may preserve healthy mouths with natural teeth.

Torquay.

Dr. T. Dunlop's report for 1920 gives the Registrar-General's estimate of the population as 34,703 for death-rate and 35,156 for birth-rate. The death-rate in 1920 was 14·7, compared with an average of 17·5 for the previous five years. The infant mortality rate was 53 *compared* with 73, and the birth-rate was 18·6 compared with 13. The death-rate from pulmonary tubercle was 1·2 in 1920 and 1·3 in 1919. The general death-rate corrected for age and sex was 12·8. The population of Torquay is, of course, exceptional. The chief occupation of the inhabitants is catering for visitors and villa residents. There is a large excess of females over males, and an unusual proportion of spinsters and females above the child-bearing age. The birth-rate is very low. Before the war births slightly exceeded deaths, from 1915 to 1918 there were more deaths than births. During 1919 there were 27 more births than deaths and during 1920 147 more births than *deaths. Of the 34 deaths* of infants under 1 year, no less than 16 are attributed to premature birth and congenital defects. In addition 24 *stillbirths* were *registered.* As regards "sanitary circumstances," there is a good supply of soft water which does not act on lead. The sewage is *discharged into the sea without* giving trouble, but attention is drawn to the need for the provision of proper sanitary bins for house refuse. A register is compiled of dairies and cowsheds satisfactory to the sanitary authority situated both within and without the borough. This seems to be a scheme worthy of imitation, as cowsheds outside a borough frequently receive very little attention in the way of inspection from the authority in whose district they are situated. "The question of the provision of an up-to-date abattoir, owing to money stringency and the high cost of building, has been deferred." Dr. Dunlop devotes a good deal of attention to discussing the dirty methods adopted in the transportation of meat and the inadequacy of *our powers of inspection* of places where food is handled and prepared.

About 45 per cent. of the children born in Torquay are unprotected by *vaccination.* The Devon County Council is the supervising authority for midwives, whilst the infant welfare scheme is under the town council. *This does not seem a* satisfactory arrangement for towns of the size of Torquay. Ten cases of ophthalmia neonatorum were notified, and as a result one of these children "has one eye in which there is apparently little vision." In last year's report Dr. Dunlop expressed the opinion that "there was a shortage of about 600 houses for persons of the working classes." The housing committee expect to complete the first 86 during the present *summer.* In the meantime "there is no doubt that there is overcrowding due to the want of housing and the high rents demanded." There were 1595 hours of bright sunshine recorded and a total rainfall of 33·50 inches.

VITAL STATISTICS OF LONDON DURING JUNE, 1921.

IN the accompanying table will be found summarised statistics *relating to* sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the *notified cases of infectious disease it appears* that the number of persons reported to be suffering from one or other of the ten diseases notified in the *table* was equal to an annual rate of 9·1 per 1000 of the population estimated at 4,531,071 persons in the middle of 1920; in the three preceding months the rates had been 9·7, 8·7, and 9·6 per 1000. Among the metropolitan boroughs the lowest *rates from these diseases* were recorded in for the birth of a child than the parental home, however squalid, would have been resented. It is difficult to say whether a change of attitude is due to the house shortage or to appreciation of the fact that labour is more likely to be a simple physiological act if it is carried on in a surgically clean environment: but it is certain that more and more mothers are showing avidity to place themselves in a home, and have to be discouraged for lack of accommodation.

There is still some prejudice among general practitioners against the infant and antenatal welfare centres. The Representative Body of the British Medical Association rejected its Committee's report under circumstances which we detail elsewhere; but this prejudice is dying a natural death now that the objects of these centres are avowedly becoming educational, advisory, and preventive rather than curative or philanthropic. No one will deny that a severe test of the existing machinery for preserving the health of infants is the present hot weather, especially since it coincides with a depreciation of the standard of living following on trade depression. The instructions issued by the Ministry of Health last week (THE LANCET, July 23rd, p. 206), on the adaptation of child welfare organisation to prophylaxis and treatment in the case of a threatened epidemic of infantile diarrhœa, are timely, and if no marked increase in infant mortality in 1921 follows on this most unusual spell of hot weather, it will be to some extent because the mothers have, owing chiefly to the welfare centres, become more learned in the art of nurture. On this one point we venture to dogmatise.

◆

THE COMPOSITION OF THE URINE DURING HUNGER.

MANY investigations have been made on the composition of the urine during hunger, but perhaps the most complete is that one carried out on two of their countrymen by Dr. N. Suzuki and Dr. N. Hasui,[1] of Kyoto. One of the subjects fasted 21·5 days and the other 14 days. A complete analysis of the urine was made daily during the hunger period, and the results compared with those obtained immediately before and after this period. Other clinical observations were also made, and the following summary represents the chief results obtained. The body weight in both cases fell very rapidly during the first six hunger days; in the second week more slowly and somewhat irregularly, and in the third week (1 case) the fall was slight and fairly regular. After resumption of feeding the increase in weight during seven days in one case was 4·1 kg., and in the other 4·15 kg. With the exception of a feeling of hunger and slight vertigo, during the whole hunger period there were no troubles complained of. The most marked decrease in the circumference of the body occurred around the level of the umbilicus, especially in the first week. The pulse beat, body temperature, and number of respirations fell, but rose again a few days after taking food. A fall of blood pressure was first observable after two weeks, and the normal pressure was restored within a week of the end of the starvation period. The tendon reflexes during the first week were normal or increased, and then became gradually weaker. In both cases the patellar reflex had noticeably decreased on the fifteenth day, and the Achilles tendon reflex had disappeared. Both gradually returned with the taking of food.

As to the urine itself, the total nitrogen in both cases from 2–6 days was just over 10 g., and gradually fell with the hunger period. The maximum, in one case (0·25 g.) and in the other (0·37 g.) per kilo of body-weight, was reached on the fourth day. At the beginning of the after-hunger period the nitrogen excretion fell distinctly, rose steeply from the fifth day, and in one case reached normal on the seventh day. The excretion of ammonia-nitrogen showed a quite regular curve. From the second day to the fifth or eighth day there was a steady rise, and then a progressive fall to the end of the experiment. After food had been taken for a week the normal value was restored. The excretion of urea in both cases ran parallel with the total nitrogen output. The amino-acid excretion showed a gradual fall till the end of the experiment. In the food period in both cases there was a sudden rise in the excretion (the food from the fifth day onwards contained albumin). The variations of uric acid are quite different from those of the total nitrogen. In one case it diminished from the first to the third day, and then rose until the end; in the second case the maximum (0·107 g.) was reached on the fifth day, and the excretion then fell to a minimum of 0·06 g. at the end of the experiment. There was a sudden rise when food was resumed. There was no marked variation in the amount of the purin-bases nitrogen. The purins in the food seem to be almost entirely excreted as uric acid in the urine. The kreatinin at first showed a fall, then a rise, followed by a fall. Kreatin was present in small amount on the first day, then it increased and remained between 0·08 and 0·11 g. On the second day, after food was taken, it fell abruptly. The fall of chlorine was very regular from the fifth to the last day of starvation, and the normal was restored on the fifth to the sixth day after the fast had been broken. The relation of the amount of chlorine to the freezing point rose gradually with the progressive hunger, while that of the total nitrogen to the freezing point showed no marked variations during the whole hunger period. The amount of phosphorus fell on the first day; from the second day it rose, and reached a maximum on the fourth; from the fifth day it gradually fell, and fell even more in the after-period, owing to the retention of compounds of phosphorus. The total sulphur fell on the first day; then followed a steady increase to the fourth or fifth day, and then a fall. On the resumption of food there was a second considerable fall in the sulphur excreted; but it rose with a diet rich in protein. The secretion of inorganic sulphates ran parallel to that of the total sulphur. The ethereal sulphates fell distinctly on the first or second day, rose on the second or third day, and then steadily fell until food was taken, when the amount gradually rose again. The neutral sulphur showed no obvious variation during hunger or the after-period. Acetone appeared on the first day and aceto-acetic acid on the second. Phenol excretion fell on the first three days; from the fourth to the seventh days the value was nearly normal. Cystin (1·0–2·0 g.) taken during the hunger period was totally oxidised and excreted in the urine as inorganic sulphate. Tyrosin given by the mouth caused on the day of its introduction in pre- and post-hunger period a distinct increase in the excretion of phenol, while if given during the hunger period the increase was first noted on the second following day. Phenylacetic acid introduced subcutaneously was excreted partly as phenylacetylglutamin and partly as phenylacetylglutaminurea; the amount of both in the pre-hunger period being about equal. In the hunger period the amount of the latter was about double that of the former.

INDEX TO "THE LANCET," VOL. I., 1921.

THE Index and Title-page to Vol. I., 1921, which was completed with the issue of June 25th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1 and 2, Bedford-street, Strand, W.C.2.

THE LANCET.

LONDON: SATURDAY, JULY 30, 1921.

The Bearings of the Staff Fund.

A COLOSSAL effort is being made to save what is known as the voluntary hospital system in this country. The Cave Committee, reporting on May 31st, said: "Is the voluntary system worth saving? We are convinced that it is." Writing to Lord SOMERLEYTON, hon. sec. of King Edward's Fund for London, on July 12th, the Prince of WALES spoke of the injury to the welfare of the sick and the enormous expense to the State which would follow if the voluntary hospital system fell to the ground. And on July 18th the annual business meeting at Newcastle of the British Medical Association affirmed with practical unanimity its belief that the voluntary method of administration is to the advantage alike of the public, medical science, and the medical profession, and should be maintained. Now such distinguished and congruous support should be sufficient to ensure the success of any system, were its principle accurately defined or indeed capable of exact definition. Probably all or nearly all of us would like to see the hospitals of the country run on the generous lines and easy finance of the first decade of the present century. Those times, alas, are gone; most honest people would add, never to return. And therefore, to be quite frank, we cannot maintain the voluntary hospital system, in which most of us have been brought up, unmodified, with all its splendid ideals and occasional defaults. And it may be useful to inquire exactly what is the essential part or principle of the system which is to be saved; to demand in fact an exact definition from those who use the term what it is of which they are speaking or thinking.

Unanimity disappears at once when we do this. A piquant contrast was afforded by the views of the first two speakers at the Newcastle meeting. Dr. F. REES, representing West Cornwall, said that anyone could see, if he chose to see, that the voluntary system was no longer capable of efficiently meeting the situation; half a million pounds of public money had just been voted by Parliament for the support of hospitals. That was the epitaph of the system. Dr. S. NOY SCOTT, representing the neighbouring constituency of Plymouth, declared that rather than have hospitals handed over to the control of the State he would see many of them closed until such time as voluntary subscriptions enabled them to be reopened. And later in the debate the B.M.A. Representative Meeting, on the invitation of its Council, differed with emphasis from the Cave Committee on one principle, that of honorary medical service, which has hitherto been regarded as a fundamental point in the system. Paragraph 50 of the Cave Report, which we print in full on p. 246, refers to the practice obtaining in some hospitals of carrying a proportion of any grants from public authorities to a fund placed at the absolute disposal of the honorary medical staff. If this practice is confined to cases where the full cost of maintenance and treatment is paid by or on behalf of the patient, not much objection, the Cave Committee thinks, can be taken to it; but any extension of the practice beyond those limits appeared to the Committee to endanger the future of voluntary hospitals. The B.M.A. proposes to extend the practice greatly beyond those limits, maintaining that the essence of the voluntary hospital system is the independent and voluntary management, this being in no way related (these four words are quoted literatim) to the conditions of service of the medical staff. As an illustration it was pointed out that the B.M.A. remains a voluntary association, although its staff is salaried. The staff fund, it might be argued, being at the absolute disposal of the staff, might be returned by them to the maintenance account, wherever this might seem equitable; in practice, however, hospital officers, like Members of Parliament, would find it invidious to return their salaries.

Here is a discrepancy which requires to be faced in order to be cleared up. We have no doubt that there are many members of the medical staffs of general hospitals who regard their honorary position as entitling them to speak with freedom and independence for the nature of the control to which they submit, and voluntary hospital committees are regarded as more prompt to act in the interests of medical education and research than committees which administer public money. No doubt the honorary staff are aware, in the words of the Cave Report, that they obtain a valuable return in the form of medical and surgical experience and the enhanced reputation which accrues to a member of the visiting staff of a great hospital. But we believe that many of them would hesitate to take the suggested tithe from patients who contribute individually or collectively to their maintenance, unless that contribution exceeds the cost of maintenance, and includes a quota for treatment. This feeling, which may or may not be well founded, rests on the tacit acceptance of the right on the part of those who pay the doctor to call the tune, and the distrust by the medical man of any sort of bureaucratic control. This has been the position in the past. The new definition, if accepted by the public, would enable the medical man to draw his income directly from his hospital work without admitting the interference or coöperation, whichever is the term preferred, of representatives of county or district councils, labour committees, Approved Societies, the Ministry of Health, or what not other trustees of funds. But will the public acquiesce in the new definition? It might be well to find out. If the professional view should prove untenable—and it would be prudent to consider the possibility of this—then, or even earlier, it might not be amiss for a few enterprising voluntary hospital committees to admit to their board certain of these representatives, and to test their ability to act in the same whole-hearted way for the public weal as their colleagues.

◆

Professional Secrecy.

ON the first day of the Annual Representative Meeting of the British Medical Association the important subject of the preservation of professional secrecy in the witness-box was discussed at length, and the proceedings were reported in our columns last week. The subject is of such profound public and medical interest that we return to its discussion at greater length. The result of the debate of Representatives was that a recommendation of the Council on the subject failed to secure support, an amendment resulting deformity and stiffness may remain indefinitely. Usually only three or four vertebræ are affected, but sometimes the whole dorsal region may be attacked. Hypotonicity of the ligaments and muscles of the sacro-iliac joints and the hips is a predominating symptom.

SNAKE POISONS AND THEIR TREATMENT.

THE cobra by reason of its wide distribution in India and the potency of its venom renders the problem of remedial treatment an extremely difficult one. It is rather surprising to learn from Major R. Knowles's address to the Royal Society of Tropical Medicine, which we reported in our issue of July 23rd, that even in untreated cases of cobra bite the mortality is not computed at a higher rate than 40 to 50 per cent.; but Major Knowles explains that the amount of venom injected may fail to reach a lethal dose through some fault in the mechanism controlling the ejection of venom, failure of the poison fangs to penetrate, or the protection of clothing. In contrast to the cobra, however, the viper, with the lightning rapidity of its stroke, greater certainty, and deadly earnestness, seldom if ever fails in its intention, and therefore allows far less chance of escape from its attack. The results of the numerous experiments carried out by Major Knowles and his colleague yield valuable information as to the minimum lethal dose (M.L.D.) and absorption period of cobra venom for the rat and the monkey (*M. rhesus*), and thus also for man, by calculation from the charted dose and death-time curve. Whereas the estimated M.L.D. for man is about 14–15 mg. of the desiccated venom and the absorption time probably not less than 10 minutes, the average yield of venom at a bite is computed at 14 or 15 times the amount required for a M.L.D. Indeed, the variation in the dose of cobra venom which may be yielded at a single bite, ranging from nil to 587 mg., is remarkable; however, provided one lethal dose is absorbed, the severity of the symptoms would not seem proportionate to the amount injected. Of the constituents and behaviour of the active principles contained in the colubrine and viperine venoms much has yet to be learnt. Their complex composition, is at present vaguely defined as comprising a "range of proteids and non-coagulable proteoses." Their toxic properties are, however, well recognised, and, for the cobra, include a hæmolysin, a cardiac stimulant, and a neurotoxin capable of paralysing the respiratory centre; whereas viperine venoms, in addition to a hæmolysin, possess a coagulin and a cytolysin or endolysin, which is rendered a most formidable lethal poison by its destructive action on the endothelial lining of capillaries and venules throughout the body. Future research by qualitative and quantitative analysis will doubtless throw light on the chemistry and relative amounts of these various toxic components of colubrine and viperine venoms, as well as on their neutralisation by antivenene—the venom-antivenom complex. We commented recently[1] on a series of investigations by Houssay, Negrette, and Sorrelli into snake venoms. Among the varieties of American, Australian, and Asiatic snake venoms studied, those of the cobra and Russell's viper were included. They were found to possess no amylolytic action, but were capable of splitting up lecithin, and gave evidence of proteolytic and strong hæmolytic power. These properties would explain the effect of neurotoxin on the respiratory centre, and of endolysin on the capillary endothelium, in colubrine and viperine venoms respectively. The specific proteolytic action of the venoms on the blood, as tested in vivo on the dog, showed that the coagulant or anticoagulant properties varied. In the early, or "positive," phase clotting by the coagulant venoms was due to precipitation of fibrinogen, but in consequence of this complete precipitation there followed a "negative" phase in which the blood was incoagulable. The action of the anticoagulant venoms, on the other hand, was due not to precipitation of fibrinogen or any formation of antithrombin, but to direct destruction of thrombokinase. Such changes may partly account for the apparently conflicting behaviour of the viperine venoms in causing both thrombosis and hæmorrhage.

The absorption period of a lethal dose of cobra venom being limited to so short a time as 10 to 20 minutes, it is obvious that remedial treatment to be effective must be extremely prompt. Of the many local remedies, apart from ligature or amputation, which have been advocated in time past, the Lauder Brunton technique of incising the bite and rubbing in crystals of potassium permanganate was for long regarded as a valuable remedy, whatever the nature of the venom. Its value depended entirely on promptness of application and on the uncertain chance that the oxidising power of the salt would be sufficient to destroy all the venom injected; in this respect its action was limited by failure to penetrate deeply enough for complete contact. Hypodermic injection of the zinc permanganate is now claimed to be far more effective in reaching the venom; better hopes even are entertained of the use of salts of the heavy metals—gold, platinum, &c.—and in particular palladium dichloride, which has such a destructive action on snake venom as to be the most successful of all local remedies yet tested. These measures are, however, but subsidiary compared with the invaluable neutralising action offered by prompt use of antivenene, particularly if given intravenously. The promise held forth by Calmette's introduction of this remedy was not fulfilled to the extent at first anticipated. There is, however, considerable hope that the process of immunisation now carried out at the Pasteur Institute at Kasauli may attain a high degree of perfection, and that the serum, improved, as Major Knowles has suggested, on the lines of concentration followed in the preparation of antidiphtheritic serum, may yield antivenene of assured potency and capable of neutralising the most lethal of venoms. Antivenene, as at present prepared, is essentially and purely a specific remedy. Whether it is possible, by a process of consecutive immunisation of the same animal against more than one type of venom, to arrive at a compound or polyvalent antivenene for universal use is at least open to doubt. The idea is, of course, no new one. Polyvalent power was claimed by Calmette for his original antivenene and was long the aim of the late Major Lamb. If proved practicable, it might solve the problems arising out of the specific nature of the various venoms. The present situation calls for coöperation with the biochemist; and we hope that the suggested trial of colloidal suspensions of the heavy metals, or the combination of concentrated antivenene with palladium dichloride, may lead to the discovery of the sure remedy of the future.

TESTS OF APTITUDE FOR A TRADE.

ATTENTION has been drawn in THE LANCET to the economic cost of labour turnover in industry and to the need for greater care in the selection of workers, not only in order to promote efficiency, but also to lighten the strain upon health caused by uncongenial employment. The problem is double: the first part is concerned with choosing juveniles possessing special aptitudes for different kinds of work, whether for engineering, for mining, or weaving; the second is concerned with ascertaining whether any particular adult applicant for work possesses the requisite knowledge and skill. The latter, although not a simple matter, is the easier task, and it is characteristic of the practical trend of American thought that while others are considering the more difficult side, they seize upon and to some extent solve the simpler. In a book recently published[1] Mr. J. Crossby of public policy. If the steps taken by a public department to procure such secrecy are insufficient without the sanction of an Act of Parliament, the legislature should intervene. By a test case we mean one in which there might be a strong combined protest on the part of the medical profession in which representative members of the public could join. At present it appears that the judge exercises a discretion against which there is no appeal and as to which there is no consistent judicial practice. It is not known, for example, how far Mr. Justice HORRIDGE would have the approval of his brother judges in the case referred to, or what the attitude of informed laymen generally may be. What is needed is certainty in order that proper constitutional action may be taken. Such, in broad outline, are the considerations which we commend to the Council of the British Medical Association in the time that remains to it before it decides to confirm as the policy of the Association the downright attitude taken up by the Representative Body—much depends upon its wise statesmanship.

Infant Mortality and the Practitioner.

IT is sometimes contended that no popular movement ever succeeds quickly and uniformly throughout a country unless the people are already uneasily groping for a lead which is overdue. Enthusiastic leaders, however, usually claim that the public awakening is not only coincident with but actually due to the crusade, and that any slackening of effort in propaganda will lead to a reversion to former indolence. The gratification caused to the zealous by the conviction that they have actually achieved a reform is a powerful stimulant to further effort; voluntary workers especially tend to regard themselves as a driving force, and would derive little satisfaction from the humbler conception of their office as that of planning the railroad on which the engine of progress can most advantageously travel. In such an important national question as that of infant mortality, however, it is surely not unprofitable to try to estimate what factor or factors have contributed to the gratifying national reduction reported by Sir GEORGE NEWMAN for 1920 in order that no effort should be wasted or misdirected. The Medico-Sociological Committee of the British Medical Association, appointed in October, 1920, chose the value of Maternity and Child Welfare Work in Relation to the Reduction of Infant Mortality as the first subject for consideration, and it is a happy coincidence that their report[1] should have been issued at a time when conferences on infant welfare, such as those held in London,[2] Brussels, and the one announced for Vienna, are claiming public attention. The Committee coöpted well-tried representatives of general public health activities and of special branches of the work under discussion to aid them in their arduous task, and a questionnaire was circulated, to which most of the answers were supplied verbally. We print on p. 248 the summarised recommendations of this Committee. The proper estimation of the influence exercised by maternity and child welfare work apart from that of other health agencies taxed its acumen. For example, one London district, the poorest and most thickly populated in the area, showed the greatest improvement in the infant mortality rate, and it was in this district that centres had been established earliest and most actively developed; again, certain other figures seemed to show that the curves of infant mortality follow practically the same course in towns where centres are active as in those where they are not. However, after considering the evidence laid before them the Committee record their opinion that "maternity and child welfare work has contributed to an appreciable extent to the reduction of infant mortality that has taken place, but . . . it is too early yet to determine what that extent has been."

Among the many tables set forth in the annual report just issued by the Chief Medical Officer of the Ministry of Health, the most arresting are certainly those showing the infant mortality rate for England and Wales since 1881. The highest figure is 156, for the five years 1896-1900, and the lowest is 80, for 1920. In 1919 the figure was 89; in 1916, the next lowest year, 91. An interesting drop from 130 in 1911 to 95 in 1912 is followed by a rise to 108 in 1913, and the average of the two subsequent years remains at this figure. Analysis of this and other tables shows that the incidence of infant mortality is heaviest in the first three months of life, especially in the first week, and that various social, domestic, and industrial conditions, notably illegitimacy, influence the infantile death-rate. Sir GEORGE NEWMAN classifies the three chief causes of death as developmental conditions, respiratory disease, and diarrhœal disease. The decrease in infant mortality recorded in recent years is referable mainly to fewer deaths from diarrhœa, partially to deaths from respiratory diseases, and, to a much less degree, from developmental conditions. Sir GEORGE NEWMAN interprets the fact that about 30 to 35 per cent. of infantile deaths are due to developmental and 40 to 45 per cent. to infective conditions as meaning that approximately half of the infant death-roll is directly preventable. In this connexion Dr. W. A. BREND's deductions from a statistical review presented to the Medical Research Council in 1917, supported by the recent investigations of Prof. ARTHUR ROBINSON,[3] are of interest. Dr. Brend considers that there is a non-preventable infant mortality of from 25 to 30 per 1000, and that these deaths, due to antenatal biological causes, occur almost entirely in the first month after birth. Undue insistence on some estimated figure as a minimum below which infant mortality could hardly be reduced would be unwise. It should be noted, however, that the attention being directed in various parts of the country to post-mortem histological examination of the tissues of stillborn fœtuses may not yield such clear results as was at one time hoped; and Prof. ROBINSON's suggestion that many deaths in utero may be attributable to biological rather than to pathological causes may well influence the lines into which research may profitably be directed in the future. But the child stillborn for lack of antenatal care, of skill in delivery, or of convenient surroundings during labour is a disgrace which calls for remedy. We hope that the schemes of the Ministry of Health for the provision of maternity hospitals and homes for normal confinements, outlined by Dr. JANET CAMPBELL in our issue of July 16th, will be prosecuted with vigour. Those who have worked as medical officers of antenatal clinics, without residential provision, did not perhaps feel the need of such provision when the centres were first opened. The mothers had to be coaxed thither with the utmost tact, and any suggestion that a residential institution could be a more fitting place to any opinion irreconcilable with the most generally accepted teachings of the day is remarkable, and he has achieved this result without resorting to the safe but dull device of stringing together platitudes. There is, however, one point on which we might join issue with him. Discussing precautions against infection, his advice to the consumptive is that "…. he should never, under any circumstances, swallow his sputum." This is a counsel of perfection. It is fairly certain that more than 50 per cent. of a consumptive's tubercle bacilli are swallowed, and this process is so continuous that were Dr. Thomson's advice to be strictly followed, the consumptive would outspit the irate llama and become an intolerable nuisance to himself as well as to his surroundings. Of course, the wholesale swallowing of nummular sputum is to be deprecated, but there are circumstances in the consumptive's career under which the expectoration of sputum into a bottle may have tragic consequences.

THE EFFECTS OF ULTRA-VIOLET RAYS ON THE EYE.

The best known dangers to the eyes from ultra-violet rays, or rather from light rich in ultra-violet rays, are inflammations of the lids and conjunctiva, such as occur in so-called snow-blindness and in "electric ophthalmia." How far and in what way the deeper structures of the eye are liable to be affected is a matter of some uncertainty. It is generally admitted that the bulk of these rays do not get through the cornea, but it has been shown that a certain proportion of them penetrate as far as the lens. According to the observations of Hallauer, Schanz, Birch-Hirschfeld and others, the transmission of ultra-violet rays through the lens is individually very different, so that some lenses scatter the bulk of the rays that reach them towards the ciliary body or elsewhere, whilst others allow them to pass through to the retina. In the former case the effect may be an interference with the nutrition of the lens and so be a factor in the production of cataract. In the latter case it is suggested by van der Hoeve that in time the injurious effect on the retina may culminate in the disease known as senile degeneration of the macula, a progressive form of partial blindness to which old people are subject. The apparent fact that there is some antagonism between this disease and cataract is looked upon by van der Hoeve as a confirmation of his view.[1] On the other hand, as no one can maintain that ultra-violet rays are the main cause of cataract, it is obvious that this argument must not be pushed too far.

In an address delivered last May to a joint sitting of the Berlin Ophthalmological Society and the German Society of Illuminating Engineers, F. Schanz, the Dresden oculist who has long interested himself in the subject of ultra-violet rays, carries the indictment against them a step farther.[2] Cases have been recorded where the onset of a colour scotoma was proved to be the result of light from a mercury vapour lamp, the affection disappearing on the light being screened by protective glass. Behr, investigating 50 patients operated on for cataract, found that the sensibility of the retina, as shown by the increased difficulty in dark adaptation, was diminished in all cases. The number of ultra-violet rays reaching the retina must have been increased by the absence of the lens, but similar increased difficulty in dark adaptation followed exposure to the rays in eyes which were intact. Schanz argues that this species of disturbance of retinal function is far commoner than is generally supposed. He suggests that the well-known prevalence of night-blindness during the war may be partly accounted for on the supposition that many of these patients had had the sensitiveness of their retinæ injured by industrial employment involving exposure to ultra-violet rays, leaving them more ready victims to fatigue. The subject does not appear to have been sufficiently investigated as yet to warrant dogmatism. Senile degeneration of the macula, however, is a not uncommon disease and any clue to its pathology and possible prevention should certainly be followed up.

ABDOMINAL PREGNANCY WITH LIVING CHILD.

Dr. E. C. Moore,[1] of Los Angeles, California, remarks that the number of recorded cases of abdominal pregnancy with delivery of a living child are uncommon, while those where the mother survived and the child lived a year or more are exceedingly rare. Of 77 cases collected by Kelly in 1898 of ectopic viable fœtus delivered by cœliotomy, 35 died within 50 hours of birth and only 7 lived for one year or more. Dr. Moore, who is of opinion that many others could be included if it were possible to obtain the necessary information, has collected 21 authentic cases of abdominal pregnancy with survival of mother and child, including Kelly's cases, and one of his own whose history is as follows: The patient was a woman aged 29, who was pregnant for the first time, although she had been married for more than five years. For about six weeks the pregnancy seemed to progress normally, and then she began to have some cramp-like pains in the lower abdomen. Operation was recommended but refused, and she remained in bed for ten days with occasional severe pain, which gradually diminished. Between the second and third months there was a slight bloody vaginal discharge. During the sixth month she had very little pain, but from that time onwards she vomited a great deal, and the fœtal movements caused much pain. At an operation performed in the eighth month the omentum and small intestine were found adherent to the anterior abdominal wall and covering a large mass which constituted the placenta, and was attached to the posterior surface of the right broad ligament and the lateral pelvic wall, and also extended up towards the liver, being attached to the omentum in this region. The uterus was about the size of an organ three months pregnant, and was pushed to the left by the placenta. The umbilical cord extended upwards to the left under the spleen, where the child was found lying free among the intestines, not surrounded by any sac. The entire broad ligament with the placenta was removed en masse. The child was a girl weighing 5 lb. 9 oz, and had no deformities. Information received from the mother about a year after the operation stated that both she and the infant were well.

Dr. Frederick Langmead, Director of the Medical Clinical Unit at St. Mary's Hospital, Paddington, has been appointed Professor of Medicine in the University of London.

The House and library of the Royal Society of Medicine, 1, Wimpole-street, London, W., will be closed during August for repairs and cleaning.

[1] Surgery, Gynecology, and Obstetrics, July, 1921.

The Council of Allied Professions.—The monthly regular meeting of the Council of Allied Professions was held at 11, Chandos-street, London, W., on July 19th. In the unavoidable absence of Dame Sidney Browne, G.B.E., R.R.C., the chairman, the meeting was presided over by Miss Rosalind Paget. Among other matters under consideration was the question of nurses and midwives being called away from their patients for jury service. It was unanimously resolved, "That it is in the interest of the community that nurses and midwives actually in the practice of their professions be exempted from jury service." It was decided to obtain the fullest possible support in the Federation of Medical and Allied Societies for this resolution and make the necessary representations. The means of utilising to the utmost extent the forthcoming journal of the Federation was also discussed, and proposals were submitted and unanimously approved whereby it would become the official organ of the societies.

Annotations.

"Ne quid nimis."

FRENCH SENATE AND TEMPERANCE LEGISLATION.

THE proposal last week in Parliament to suspend the activities of our Liquor Control Board leads to an instructive comparison with the very different conditions ruling on the other side of the Channel. A frequent correspondent writes: The French Senate has refused to confirm the proposal accepted by the Chamber of Deputies to reduce the tax on wine. This involves an important social question which should be of special interest to the advocates of temperance. Of course, there is no reckoning with the contradictions or inconsistencies that may result from the financial stress due to the war; but, in its present decision, the Senate has acted against tradition and expectation, and against what some consider wise policy. When, some 40 years ago, the vineyards of France and Switzerland were devastated by the phylloxera, the increase of drunkenness, insanity, and crime was so marked that the Senate appointed a special commission to inquire into the cause of this evil. We explained at the time, and on several subsequent occasions,[1] the conclusions arrived at by the Commission, which were endorsed by many Congresses of Hygiene and similar scientific gatherings, both national and international. It was generally agreed that the evils of drunkenness were almost unknown in those countries where natural wines were plentiful and cheap, for the desire and need for drinking spirits did not arise. It was because this happy condition was destroyed by the phylloxera that a rapid increase of intemperance and its attendant evils caused the Senate to take action. The vineyards were saved by grafting French vines on American roots. Grapes became abundant again, real and cheap wines took the place of imitations made with dried currants, bad alcohols, and other unwholesome ingredients, and drunkenness abated. This wholesale object-lesson gave rise to a widespread view that if populations were contented to drink clean water and light and pure wine and beer, the demand for strong spirits would die down, and there would be little drunkenness. Cider, perry, and hydromel are accepted also by the French definition as hygienic drinks. Light wines are, of course, the strongest, for they may contain as much as 12 or 13 per cent. per volume of alcohol. But then if drunk in large quantities, as for instance, in very hot weather, they are generally mixed with at least half as much again of water. In course of time practical action followed theoretical discussion, and a law was enacted by which towns and communes were allowed local option in carrying out temperance legislation. Paris led the way by a heroic resolution to abolish altogether every tax on hygienic drinks. In 1897 the municipal income of Paris amounted to £6,200,000. The abolition of the tax (octroi duty) on hygienic drinks would have reduced these receipts to £4,400,000. Nevertheless, Paris was so determined to do away with drunkenness and the disease of alcoholism, that it consented to lose this source of revenue, thus sacrificing more than £2,000,000 annually. The results were satisfactory. In good vintage years wholesome natural wines could be purchased retail and within the walls of Paris at from 1½*d.* to 2*d.* the pint, or 15 to 30 centimes the litre. So there was no excuse for drinking spirits.

The war shattered all these temperance measures. Wine became dear, and taxes had to be re-imposed. In the course of time, however, the Chamber of Deputies thought it might venture on a small and first step towards restoring the former position, which had conduced to temperance. A Bill was recently introduced and adopted by the Chamber of Deputies to reduce the taxes that had been re-enforced upon hygienic drinks. Thus the tax on wine was to be reduced from 19 fr. to 12 fr. per hectolitre; on cider from 9 fr. to 6 fr., and on beer from 2 fr. 60 c. to 1 fr. 65 c. per hectolitre. But in the Senate it was objected that this would mean a loss of revenue of 461,000,000 fr. for the State and 51,000,000 fr. for the communes. Though the Senate had in former days been the means of initiating such measures in favour of hygienic drinks, it now declared that, temperance or no temperance, neither the State nor the local authorities could afford these financial sacrifices. Thus the Senate on July 9th threw out the Bill, but only by a majority of 155 votes against 136. We may, therefore, anticipate that the matter will come up again at no very distant date. In the meanwhile, it is very desirable that further reliable informations and statistics should be forthcoming. All countries will be interested to know to what extent the more recent increase in the cost of wine has produced results similar to what was noticed when the phylloxera destroyed the vineyards.

SYPHILITIC BACKACHE.

BACKACHE when it occurs in syphilitic infection is apt to be persistent and intractable. Dr. Joseph Victor Klauder,[1] assistant professor of dermatology and syphilology at the Graduate School of the University of Pennsylvania, who records four illustrative cases, discusses the nature of syphilitic backache according as it is a symptom of specific involvement of the spinal cord, lumbar muscles, or vertebræ. In most instances it is a symptom of involvement of the spinal cord, the condition being meningeal in origin and due to irritation of the posterior sensory roots. The posterior surface of the cord is more frequently involved than the anterior surface, and the meningitis is more extensive and more intense in this region. It is usually most severe in the dorsal segment, where the spinal cord offers least resistance. Syphilitic spinal meningitis may be acute, subacute, or chronic, and may persist from the early secondary period until many years later. In addition to backache, other sensory symptoms of meningitis may be present, such as girdle-pain, hyperæsthesia, and paræsthesia. The tendon and skin reflexes are increased. Motor irritation is manifested by tension in the muscles. Clinically there is rigidity of the back combined with localised or diffuse tenderness on percussion of the vertebral column. The spinal fluid always shows a positive Wassermann reaction and a more or less marked pleocytosis according to the severity of the meningeal involvement. In backache due to syphilis of the lumbar muscles the underlying condition is rather an acute spirochætal infection than a syphilitic myositis, which chiefly affects the flexors of the arms and legs. Backache due to syphilis of the vertebræ is rare, the cervical region being most frequently affected. Of 55 cases collected by Neumann in 1904, the cervical region was affected in 65 per cent., and the dorsal and lumbar region in 31 per cent. In syphilis, in contrast with tuberculosis, the spinous and transverse processes are more apt to be affected than the bodies of the vertebræ. The pathological conditions are periostitis and osteitis, which may lead to necrosis and the production of sequestra. There is less likelihood of the formation of a cord abscess than in tuberculosis of the vertebræ. Syphilis, however, as in one of Dr. Klauder's cases, may rouse dormant tuberculosis into activity, so that this possibility should be borne in mind in the presence of vertebral involvement in a syphilitic patient. Synovitis of the spinal joints, which Dr. Klauder regards as perhaps the commonest lesion in syphilis of the spine, may also give rise to backache. Syphilitic synovitis occurs early in the disease, although the

[1] Archives of Dermatology and Syphilology, June, 1921.

Journal once a month, and for dealing with medical matters from the students' point of view took no definite form, the following resolution being put and lost:—

That, in order to stimulate the interests of senior students of medicine in the work of the Association, and so tend to secure their adherence at the outset of their careers as practitioners, the B.M.A. institute a student class of members at a reduced fee, with the privilege of attending scientific meetings.

Expenses of Representatives.

A proposal to pay the out-of-pocket expenses of representatives who attend meetings of the Representative Body was withdrawn on the Treasurer pointing out that the minimum cost would be £2000.

State Reward for Scientific Research.

On the invitation of Newcastle-on-Tyne the meeting put on record its regret that the British Empire, with its world-wide possessions, cannot suitably reward the men who have done so much to render life supportable in its many climates, and instructed the Council to take all possible steps to induce H.M. Government to provide efficient reward for scientific work carried out in the interest of the State.

The Voluntary Hospital Principle.

A long debate on hospital administration was opened by the passing with practical unanimity of a motion proposed by Mr. N. BISHOP HARMAN, Chairman of the Hospitals Committee, to the effect:—

That the Representative Body desires to record its belief that the voluntary method of administration of the voluntary hospitals of the country is to the advantage of the public, medical science, and the medical profession, and that it should be maintained.

Only a single voice was raised to point out that the actual Government grant of half a million pounds shows the voluntary system to be incapable of keeping hospital administration efficient. Mr. Harman stated that the principle of voluntary administration would not be impaired in any way by payment of the medical staff. Freedom and elasticity were inherent in the voluntary system, which was more under the influence of the medical profession, and more appreciative of scientific work and research.

A second motion, that necessitous persons should continue to be treated free, was amended and passed in the form:—

That inability to pay for adequate treatment shall be the consideration for the admission of all patients for hospital treatment—

after it had been pointed out that the word "necessitous" is now generally accepted in a special sense in regard to the Poor-law, whereas numbers of the "new poor" are unable to afford adequate treatment outside the hospital. A rider to the effect that hospital treatment should not be given gratuitously to patients maintained in whole or in part by public funds was lost by a considerable majority, after an appeal by Dr. A. C. Farquharson, M.P., to enunciate the voluntary hospital principle, and leave the details for their voluntary committees to define.

Municipal and State Grants.

The third motion by the Chairman of the Hospitals Committee was as follows:—

That it is undesirable that the voluntary hospitals should be subsidised by the local rating authorities, except in so far as payment is made for the examination and the care of patients for whom these authorities are responsible.

The motion was accepted by the meeting in this uncompromising form, after refusing the qualification: "unless it be understood that such subsidy does not give the rating authority the right to interfere with the administration of the hospital."

In view of the materialisation of the grant to hospitals by the Ministry of Health the following motion and amendment were not dealt with, but were referred back to the Council:—

Motion: That in times of financial difficulty it is desirable that the voluntary hospitals should be subsidised by the central Government, and that such subsidy in the case of any individual hospital should take the form of a contribution proportional to the income received by the hospital from voluntary and other contributions. The subsidies here proposed should be made through some central hospital fund.

Amendment (by Brighton): That, at the present time of financial difficulty, it is desirable that the central Government should subsidise voluntary hospitals. The subsidies here proposed should be made through some central hospital fund, and should not carry the right of any control in the management beyond that allowed to an ordinary private subscriber.

A fifth recommendation of the Hospitals Committee, expressing the view—

That greatly extended support for voluntary hospitals should be sought from employers and insurance companies, seeing that they benefit largely both directly and indirectly by the services of the voluntary hospitals

was adopted after discussion, in which it was pointed out that the provenance of hospital funds was a matter more for the general public than the medical profession to decide.

Recommendations six and seven of the Hospitals Committee were then passed in the following form:—

That every patient of a voluntary hospital who is able should make a contribution, during treatment, towards the cost of maintenance, unless the contributory method of subscription is adopted as essential in industrial areas. In view, however, of the increased cost of maintenance, &c., the Representative Body considers that the contributory rates paid by workmen should be materially increased.

That, where voluntary hospitals provide accommodation for paying patients, no fixed rate of payment for professional services rendered to such patients should be established; the fees so payable to remain, as at present, a matter of arrangement between patient, family physician, and consultant.

An amendment to fix a maximum fee was decidedly rejected.

Formation of Medical Staff Fund.

Much time was given to a discussion of the allocation of funds to the medical staff in connexion with any contributory scheme, and the eighth recommendation of the Hospitals Committee was finally agreed to in the following revised and extended form:—

That in the event of decisions being taken which would lead to patients (other than paying patients referred to in foregoing Minutes) paying, in part or in whole, the hospital maintenance fees, either individually or by some contributory method, or with the addition of rate aid or State aid, or by a combination of two or more of these methods, a percentage of all such payments should be passed into a fund which can be allocated in any manner which such honorary medical staff may determine.

That when the board of management of a voluntary hospital enters into a financial arrangement with a public authority, an employer of labour, approved society, insurance company, or under a contributory scheme, for the reception of patients, such arrangement should be taken to cover the cost of maintenance and treatment, and a percentage of all such receipts should be passed into a fund which is at the disposal of the honorary medical staff of that hospital.

That it be an instruction to the Council to bring this resolution to the notice of the secretary and the senior honorary medical officer of each voluntary hospital, with a request that the policy therein outlined be adopted by the board.

There were about 15 dissentients to this resolution, some members feeling strongly on the one hand that it was impolitic to take a tithe of small payments from prospective patients, but that hospital boards in making any arrangement with paying bodies might reasonably contract for treatment as well as for maintenance. The medical profession, it was alleged, was willing to do philanthropic work in at least an equal proportion to that of other sections of the community.

Staff Fund and Voluntary Principle.

At this point a resolution proposed by Chairman of Council was taken, disagreeing with para. 50 of the Cave Report, which runs thus:—

"In connexion with the grants by public authorities it appears desirable to refer to the practice which obtains in some hospitals of carrying a proportion (from 10 per cent. to 20 per cent.) of these grants to a staff fund which is placed at the absolute disposal of the honorary staff. In some of

Chapman sets forth how, during the war, the recruiting authorities in the United States tackled the question of selection. There were many recruits to see and to classify, but few to act as assessors. Methods were devised by which the interviewing and classification could be carried out by persons who did not need to possess knowledge of the multifarious crafts concerned. Definite tests were devised:—An oral test in which clearly thought-out questions had to be answered in a definite way and were marked accordingly. A picture trade test was used in which the names and use of tools pictorially presented had to be given. Another group included performance tests in which work had to be performed not only in a definite way but in a definite time. A written group test was also employed in which the right answer to a question out of four alternatives had to be selected. The claim is put forward that the Army authorities succeeded, by the use of these tests, in grouping recruits according to their abilities in a way which saved sending overseas as mechanics or skilled craftsmen those who had no real knowledge of the work they claimed to know about and would be required to do; and, further, after testing the methods used against the somewhat haphazard methods in vogue in industry, that unskilled examiners, following out these methods, obtained far better results than skilled foremen and the like who usually undertake the duty of engaging labour. Mr. Chapman's application of these conclusions to labour selection should be studied in this country by those controlling its industries, and also by members of the profession interested in industrial hygiene.

THE SUBCUTANEOUS INJECTION OF VACCINE LYMPH.

THE possibility has often been discussed of obtaining protection against small-pox by injecting vaccine lymph subcutaneously instead of the present method of superficial scarification of the skin and rubbing in the lymph. It is contended that if there were no vesicles on the skin septic germs would be unable to find a point of entrance into the patient's system. Dr. S. A. M. Copeman, in 1898, discussed this question in his Milroy lectures and described experiments he had made by injecting subcutaneously vaccine lymph, diluted with normal saline solution, into monkeys, the result being that "some degree of protection was obtained against vaccinia" and presumably therefore against small-pox. Other investigators on the continent by injecting vaccine lymph into bovines and horses found that "by means of a generalised influence over the system, although unaccompanied by production of local results, it is possible to obtain immunity from subsequent vaccinia." These experiments, however, do not seem to have been very convincing and the subject was allowed to drop. It has now been raised again, this time in India, by Lieut.-Colonel C. F. Fearnside, I.M.S. (retired), Medical Superintendent, Central Jail, District Medical Officer and Sanitary Officer, Coimbatore, who contributes a paper "On the Injection of Lymph Subcutaneously as a Protection against Small-pox," to the recent Special Indian Science Congress Number of the *Indian Journal of Medical Research*. This observer has long been dissatisfied with vaccination by scarification, especially in view of the opportunities in India for acquiring septic infection. It is common, he says, for ignorant Indian mothers, as soon as the vaccinator's back is turned, to try to prevent the vaccination taking effect, and for this purpose the wet lymph is wiped off the child's arm with the mother's dirty fingers. All sorts of objectionable materials are applied to the vaccinated places, after the vesicles have formed, including the ever-blessed cow-dung poultice. The lanolated calf lymph in use in the Madras Presidency is prepared at the King Institute, Guindy, where it is put up in leaden tubes with a cap. To a spare cap Colonel Fearnside soldered on an ordinary hypodermic needle which, after being sterilised, was screwed on to a tube of lymph from which the protecting cap had been removed. The patient's arm was touched with a drop of tincture of iodine and the needle inserted beneath the skin. By pressure on the leaden tube a small quantity of lymph was forced through the needle beneath the skin. Four injections were made in each case. On withdrawing the needle, the point of exit was touched with tincture of iodine. This rough instrument does not allow of the amount of lymph injected being measured. The effect of these injections is the production of knotty swellings under the skin varying in size from that of a pea to that of a small almond, and they may persist for some time. During the last few years more than 800 prisoners in Coimbatore jail have been vaccinated in this manner. There was some focal reaction in 82 per cent. of these cases but no superficial vesiculation except where the needle had scratched the skin; all cases showing this reaction were classed as successful. Recently 12 of the prisoners were revaccinated in the usual way by scarification of the skin, but in no instance did any of them "take." This was regarded as a proof that they were protected by the previous hypodermic injections. At Colonel Fearnside's suggestion, Dr. F. M. Gibson, Director of the Guindy Institute, carried out some experiments with the subcutaneous injection of lymph on calves, but the results on the whole were not very satisfactory, though Dr. Gibson admits that such injections do confer a certain amount of immunity against vaccinia. This immunity, which is likely to be only of a temporary character, is in proportion to the amount of lymph injected. The knotty swellings are inflammatory nodules formed round the injected foreign matter, and are not due to growth of the injected lymph since material taken from the nodules early (in 86 hours) and late (in 168 hours), failed in every instance to produce vaccinia when rubbed into the scarified skin of calves. Colonel Fearnside states that he is not altogether satisfied with these experiments at the Guindy Institute, and suggests that further investigations should be undertaken in view of the great benefits that might be expected to follow the employment in India of a method of performing vaccination which would be free from the danger of septic infection.

MEDICAL BOOKS FOR LAY READERS.

CHRONIC diseases may be roughly classified according as they do, or do not, excite medical writers to publish books for the perusal of the patient. Pulmonary tuberculosis and neurasthenia belong to the first class, syphilis and diabetes to the second. It seems a little unfair that the benefits of this class of popular instruction should be so unevenly distributed, and to the medical writer aspiring to issue yet another book full of advice to consumptives, we suggest a preliminary study of a standard work such as Lawrason Brown's "Rules for Recovery from Tuberculosis," followed by consideration of the question: "Can I excel this book in matter, manner, or both?"

In his handbook[1] on the prevention and home treatment of tuberculosis, Dr. H. Hyslop Thomson has shown a sufficiently intimate knowledge of his subject, and discriminating appreciation of the factors which ultimately determine the fate of the patient to make his book worth writing and reading. With wisdom not always shared by other members of the tuberculosis service he writes: "Once the acute stage of the disease has been passed, the patient who relies upon his thermometer and knows how to use it intelligently, is the one who is least likely to relapse and who has the best prospects of recovery and of permanent arrest of the disease." Considering that the problem of tuberculosis bristles with controversial points, the manner in which Dr. Thomson threads his way through his book without committing himself

---

[1] Tuberculosis: Its Prevention and Home Treatment. Second edition. By H. Hyslop Thomson, M.D., D.P.H., County Medical Officer of Health and County Tuberculosis Officer for Hertfordshire. London: Henry Frowde and Hodder and Stoughton. 1921. Pp. 99. 4s.

This was withdrawn when it became clear that its enforcement would require a bond in the agreement, instituting the appointment, as well as legal enactment, to give effect to it.

Fee for Notification of Infectious Disease.

The Representative Body once again authorised its Council to press for the restoration of the 2*s.* 6*d.* notification fee "forthwith and without delay."

Report on Maternity and Child Welfare.

A weighty report on the value of maternity and child welfare work, in relation to the reduction of infant mortality, was brought in by the Medico-Sociological Committee. Dr. E. R. Fothergill acted as chairman of this committee, and Dr. Alfred Cox as secretary, and a number of members were coöpted representing voluntary child welfare associations. The report, issued in the supplement of the *British Medical Journal* for July 2nd, has been reprinted in pamphlet form at 3*d.*, obtainable from the offices of the Association. Its conclusions, signed by every member of the committee, run as follows:—

1. Maternity and child welfare work has contributed in an appreciable degree to the reduction of infant mortality that has taken place, but it is too early to determine to what extent it has been effective.

2. The effect of many of the causes of infant mortality can be lessened by the education of women at centres and in their homes.

3. The educational work amongst the mothers on the racial poisons (alcohol, syphilis, and tubercle) and on the influence on infant mortality of pollution of the air by smoke and other impurities with the consequent deprivation of sunlight, should be encouraged and extended.

4. The instruction of the elder girls at school in homecraft and mothercraft should be developed and encouraged.

5. Every effort should be made to improve the economic position and prospects of midwives and midwifery nurses; and encouragement should be given to them by local authorities wherever there is difficulty in securing a sufficient supply.

6. The provision of sufficient hospital accommodation for diseases of pregnancy and difficult confinements, and maternity homes for normal confinements which cannot conveniently be conducted in the patients' homes, should be made general as soon as possible.

7. The primary and main object of maternity and child welfare centres should be educational, preventive, and advisory; no treatment should be given for conditions which, in the absence of the centre, would be recognised as calling for the attendance of a medical practitioner; it is against the best interests of the centres to encourage women to go to the centre for what they can *get* rather than for what they can *learn*.

8. There are advantages to the work in associating with the centres a body of voluntary workers, but the whole of the work should be under the control of the medical officer of health in order that all the preventive agencies may be coördinated.

9. The support of the local doctors, nurses, and midwives can and ought to be secured. This can be done if (*a*) it is made clear that the sphere of the centres is restricted as recommended above, and (*b*) if members of these professions are represented on the statutory committee and the committees controlling the centres, these representatives being nominated by the local organisations of these professions wherever such exist.

10. The experience of the "family doctor" would be useful in the work at the centres; but that practitioners accepting the appointments must have knowledge of and a real interest in the work; the appointment should be for a long enough time to be administratively convenient; and those appointed should clearly realise that in accepting the post they must undertake to carry on the work irrespective of other claims on their time.

11. For every mother and child up to 5 years of age there should be available domiciliary attendance by a family doctor.

12. In order that medical practitioners should be fully equipped for maternity and child welfare work it is desirable that the medical student should be educated in and be encouraged in the practice of duties in relation to (1) personal and domestic hygiene, and (2) industrial hygiene and other spheres of preventive medicine.

There was no opportunity at this late hour in the meeting of considering the bearings of so far-reaching a document, and after some dissent had been expressed it was decided to take no attitude towards the report at present.

Election of Officers.

Voting took place on Saturday, July 16th, for the four members of the Representative Body chosen by them to serve on the Council for 1921–22. The members elected were Dr. H. G. Dain, Dr. R. Langdon Down, Dr. J. A. Macdonald, LL.D., and Mr. E. B. Turner. On Monday, July 18th, Sir Clifford Allbutt was elected a vice-president of the Association in recognition of his services as president from 1916–21.

THE ANNUAL GENERAL MEETING.

The annual general meeting opened in the King's Hall, at 2 P.M., on Tuesday, July 19th, when the retiring President, Sir **CLIFFORD ALLBUTT**, gave a brief valedictory address in which he set out the reward of his long service already received in new friendships, and an intimate knowledge of the working of the Association from the inside. He then inducted his successor, Prof. **DAVID DRUMMOND**, who felicitously compared the annual gatherings of the Association at different centres to the passage of the soul through life, changing its body but retaining the spirit of its being. Newcastle had ploughed its own furrow and attempted to make the Association meeting a success on its own lines. After approval of the minutes, and appointment of auditors, the President introduced Sir **WILLIAM MACEWEN** as President-elect for 1922–23. Prof. **R. A. BOLAM**, as Chairman of Council, then tendered hearty thanks to the retiring President, which were carried by acclamation.

At the adjourned meeting in the evening Prof. **DRUMMOND** delivered his presidential address, entitled "The Medical Profession: a Horizon of Hope," an abstract of which appeared in last week's issue. Prior to the address Mr. **R. J. WILLAN**, hon. local secretary, introduced to the President the foreign guests of the Association, Prof. **MURK JANSEN** of Leiden, and Prof. **H. BROOKER MILLS** of Philadelphia. A vote of thanks for the address was proposed by Sir **JAMES BARR**, who veiled under a playful guise a serious criticism of the emphasis laid by the President on the end-results of disease rather than on earlier remediable changes. This done, the Association's gold medal of merit was handed to Sir **DAWSON WILLIAMS** for his distinguished services to the Association and the medical profession as Editor of the *British Medical Journal*. A substantial cheque was handed to Dr. **J. A. MACDONALD**, past Chairman of Council and a former chairman of the Representative Meeting, as a token of friendship and appreciation. Dr. Macdonald, in returning thanks, referred to the growth of influence of the Association since its reconstruction in 1900.

The reception at the Assembly Rooms, which followed the address, was noteworthy for the number of medical women who attended in doctors' gowns.

Honorary Degrees Conferred at Durham.

At a special Convocation held in the Castle Hall, Durham, on the afternoon of Thursday, July 21st, honorary degrees were conferred upon a number of distinguished medical men. Prof. **DAVID DRUMMOND**, Vice-Chancellor of the University, occupied the chair, and was supported by members of the Senate. Sir William Macewen, Sir Thomas Oliver, and Sir Humphry Rolleston received the D.C.L., while the D.Hy. was conferred upon Dr. T. Eustace Hill and Dr. J. Wilkie Smith, the D.Sc. upon Sir Arthur Keith, the D.Litt. upon Sir Dawson Williams, and the M.A. upon Dr. Alfred Cox.

The Durham visit coincided with that of a group of overseas professors attending the Oxford Conference of the Universities of the British Empire. The presidents or deans of the universities of Alberta, McGill, Toronto, Bombay, and Madras were present, the two latter being the guests of Dean Welldon.

The Annual Dinner.

At the annual dinner held at the Assembly Rooms Club on Thursday evening, July 21st, Prof. **DRUMMOND** presided, and it fell to Dean **WELLDON** to propose

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

NEWCASTLE AS A PLACE OF MEETING.

NEWCASTLE-ON-TYNE is an interesting place for a medical gathering, and Prof. Drummond was right in suggesting that the local setting would give a characteristic tone to the meeting as a whole. The city and county of Newcastle has an estimated population of 286,000, not including the twin city on the other side of the Tyne, which is separate in sanitary and every other kind of administration, although everything except the actual houses pass freely across the bridges and make the health problems identical on the two sides. The birth-rate of Newcastle in 1920 was 28·0, and the death-rate 14·0, an exact half, a portent in itself to the southerner. The infant mortality rate in the same year was 101, the zymotic death-rate actually under 1. 837 cases of tuberculosis were notified during 1920, 593 of phthisis, 244 of other forms, being an attack-rate of 3·0 per 1000, with a death-rate of 1·64 per 1000; evidently the latter figure is the nearer the truth. Cancer was credited with 244 deaths, measles with 42, puerperal septicæmia with 5.

The housing problem in central Newcastle is complicated by the remarkable feature of the Town Moor, an immense open space belonging to the city which thrusts its nose to within half-a-mile of the river, and produces much the same problem as arises in New York. Water-carriage of drainage has, however, been introduced throughout the congested isthmus, some 5000 privies remaining for the present in two more distant areas lately taken over by the city. The town itself is full of relics of Tudor and Norman times, mixed up with the less noble mid-Victorian architecture, and along the Carlisle-road there soon appear traces of the great Roman Wall, the stones of which have been appropriated for domestic purposes in the section from Newcastle to Wallsend. Along the Tyne the amount of shipping, notable in ordinary times, is immensely enhanced at the moment by the number of huge cargo boats of many nations hung up by the coal crisis, and the many unfinished hulks of liners the despatch of which has been delayed for various reasons. A fleet of the new concrete boats was much in evidence.

The present is an anxious time for the sanitary administration of the city. The Corporation in a very natural spirit of economy has seen fit to reduce the actual estimate of the Sanitary Committee by £19,000, which has necessitated the release of 8 out of 20 health visitors and of a tuberculosis nurse. Visiting of pre-school children has been discontinued, and a number of infectious cases are treated at home on account of the reduction of fever beds. Fortunately hygienic indiscretion rarely brings immediate disaster, and it may be hoped that, after the stimulating visit of the British Medical Association, the city fathers may see their way to square the municipal balance-sheet by economies on less essential industries than those of public health. Dr. Harold Kerr, the medical officer of health, is keenly alive to the value of friendly coöperation, and, we believe, has introduced the principle of a weekly round table for discussion of health questions by the five full-time medical officers.

Figures given at the annual meeting of the Newcastle Insurance Committee, held during the medical week, show that there are 110 practitioners and 48 chemists on the panel, with 62 shops supplying drugs to insured persons, and somewhere about 118,000 insured persons. Councillor David Adams, vice-chairman of the Committee, is a convinced believer in the National Insurance Act as the proper basis upon which to build up a unified medical service in this country.

The city is happy in possessing so excellent a hospital as the Royal Victoria Infirmary, rebuilt on modern lines through the generosity of Lord Armstrong, and admirable alike in position and arrangement. But with a total of 160,000 out-patient attendances and nearly 10,000 in-patients in 1919, the city is considered gravely under-hospitaled, in spite of the fact that the adjoining Ministry of Pensions War Hospital, with its well-arranged bathing and massage department, will be handed over to the civil authority within a year or two.

Visitors to Gateshead were also aware of the urgency of local politics. The Guardians, having incurred a large outlay in relieving distress among miners' wives and children during the recent crisis, had levied a special rate of 1s. in the £ for immediate payment, with the result that a large number of ratepayers are making a strong protest, and an open-air meeting at Low Fell was largely attended.

ANNUAL REPRESENTATIVE MEETING.

(Concluded from p. 198.)

MONDAY, JULY 18TH.

Admission of Non-Members to Sectional Meetings.

ON a motion proposed by Dr. F. C. MARTLEY (Kensington) the question was raised of the exclusion of all but members of the Association from the scientific meetings. It was pointed out, however, that certain civil servants or members of the General Medical Council might be thus debarred from attending, and there was, of course, no wish to eliminate Americans. In the past even presidents had joined the Association on nomination. The motion was finally passed with a few dissentients in the following form:—

> That it be an instruction to the Council to provide that no member of the medical profession who is eligible for membership of the Association, but who is a non-member of the Association, shall take part in the sections of the annual meeting, unless in such circumstances as the Arrangements Committee may consider exceptional.

Subscription to the Association.

After the Treasurer had pointed out that the balance-sheet for the past year showed the necessity of raising the subscription to the Association, the followed revised rate was unanimously adopted, to come into force on Jan. 1st, 1922:—

A.—As to members resident in the United Kingdom.
- (i.) For a member of the Association of not less than 10 years' standing as such who has definitely and permanently retired from the active practice of the medical profession, and has signed and transmitted to the treasurer a declaration to that effect—2 guineas.
- (ii.) For any member of not less than 10 years' standing—2 guineas.
- (iii.) For a member admitted to membership before the expiration of two years from the date of his registration under the Medical Acts—1¼ guineas until the 31st December next occurring after the expiration of four years from the date of such registration.
- (iv.) For two members being a husband and his wife residing together—1½ guineas.
- (v.) Except as otherwise herein provided—3 guineas.

B.—As to members resident outside the United Kingdom.
- (i.) For any officer of the Royal Naval Medical Service, the Royal Air Force Medical Service, the Army Medical Service, or the Indian Medical Service—2 guineas.
- (ii.) For any other member—1¼ guineas.

But in view of the difficulty of determining in any particular year the place of residence of a member of the Services, it was remitted to the Council to consider the advisability of a flat rate of £2 2s. for all active service members.

Student Class of Membership.

Various suggestions were made for making the Association more attractive to medical students. Unfortunately the annual meeting can only be held at a teaching centre when the school is not in session. Proposals for issuing a students' number of the

Concurrent Meetings.

The Temperance Breakfast.—A large number of delegates attended a breakfast on Thursday, July 21st, given in the Grand Assembly Rooms by Sir George Hunter, D.Sc., Vice-President of the National Temperance League. Sir A. Pearce Gould, who made a special journey from London to attend, said that it was a matter of common knowledge how rapid had been the decline of alcohol as a therapeutic agent during the last 30 years. Pharmacologists now agreed that alcholol was of value only as a narcotic, and not as a stimulant. He submitted that the medical profession had not yet shouldered its full responsibility in regarding the alcohol question as a problem in biology. We now had useful scientific knowledge of the effect of alcohol in medical, social, and economic aspects, and a simple, clear, and faithful witness to scientific truth on the part of medical men would, he was assured, meet with a great response. Rev. Courtenay Weeks, M.R.C.S., who submitted a resolution, desired that the fullest advantage should be taken in schools of the syllabus on the hygiene of food and drink recently issued by the Board of Education. Lady Barrett and Captain W. E. Elliot, M.P., also spoke briefly and effectively.

Irish Graduates' Association.—The forty-first summer meeting of the Irish Medical Schools' and Graduates' Association was held at the County Hall, Newcastle, on Wednesday, July 20th, the chair being occupied by Dr. J. A. Macdonald, in the absence of the president, Major-General W. W. Kenny, A.M.S. The best way, Dr. Macdonald said, to promote good fellowship between Irishmen was to give them opportunities of meeting socially. The Association wished to break down the barriers still preventing the highest diplomates of Irish Royal Colleges from candidature for honorary appointments at English general hospitals, and was determined to go on until successful.

Conference on Cripples.—During the Association's meeting an important conference took place in the library of the Royal Victoria Infirmary on the treatment and education of physically defective children, under the joint auspices of the Newcastle Invalid Children's Aid Association and the Central Committee for the Care of Cripples. Lady Parsons presided, and the morning session was devoted to the curative, the afternoon to the administrative, aspect of the question. Some account of this conference will be given later.

Local News Items.

Newcastle medical men and other local residents placed their motor-cars at the disposal of the representatives all day on Sunday, July 17th. Lunch was taken at Rothbury after a walk along the rocky bed of the Coquet. Lord and Lady Armstrong personally conducted the party over their house at Cragside, with its wonderful rock garden. In the afternoon the route was by Alwinton and Elsdon Common, over the lower slopes of Cheviot, with tea at Otterburn, hard by the famous mill of soft woollen shawls. Trout streams, herons, black-faced sheep, and remains of extensive Canadian tree-felling were among the natural objects shown. The occasion was one of happy comradeship, which had its effect on the resumed Monday meeting.

The Medical Institute, at 7, Windsor-terrace, generously placed at the disposal of visitors during the medical meeting, was formally opened on Tuesday, July 19th, by Sir Clifford Allbutt, Prof. David Drummond presiding. The Institute is the gift of Dr. J. Wilkie Smith, to the memory of his son killed in the war, and is arranged as a club for local medical men, with billiard and luncheon rooms, lounge, a meeting room capable of seating 40 or more, and several bedrooms reserved for short period visitors.

The opportunity was utilised by members of seeing the scientific study being given in Newcastle to rescue work in mines. On several afternoons Mr. F. P. Mills, chief officer of the Northumberland and Durham Colleries Fire and Rescue Brigade, gave a demonstration at the Scotswood Road Station. The fire brigade responded to a call in 20 seconds. An imitation pit shaft is being sunk where prospective colliers can go through a preliminary training in darkness and exposure to gases, learning there the confidence which is a chief safeguard against avoidable accident. Sir James Cantlie's suggestion to found a college of ambulance in Newcastle met with a warm reception locally. The secret of success in first-aid lay, he said, in improvisation.

Sir James Cantlie's exhibit of the Thomson machine, being a table designed to enable an armless man to perform all the ordinary occupations of life, attracted a large amount of local interest. Designed by a gasfitter, this marvellous table was shown in action, a man bereft completely of both upper limbs eating an egg, lighting and smoking a cigarette, writing a letter and sealing it in an envelope. The demonstrator had in fact taught himself to write on the machine, having previously been illiterate.

During the gathering was held the annual meeting of the Newcastle Industrial School, of which Mr. J. Alaric Richardson is chairman. The Committee is happy in having acquired a country mansion, Axwell Hall, eminently suitable for the proper segregation and education of truant boys, and surrounded by ample grounds. Officially truancy is on the decrease in Newcastle, although the streets and parks do not quite confirm this impression.

Members of the general press attending the representative meeting admitted that they found the discussions hard to follow, the motions and amendments not always bringing out clearly the points on which the meeting wished to express its opinion. In concerning itself with the sources of hospital revenue it was suggested that the matter was actually outside the province of the medical profession, although to take an interest in it was praiseworthy. Elocution was felt to be at a low ebb as compared with other professional gatherings, but the brevity of spokesmen was highly commended. Favourable comment was made upon the plan of numbering representatives' desks with a large figure, thus making identification easy.

Where so many contributed to the success of the meeting and to the happiness of the guests it would be invidious to mention names other than those of certain members of the General Executive Committee who were sectional chiefs. Dr. W. J. Durant organised the excursions, Dr. N. MacLay the annual dinner and catering generally, Dr. E. Farquhar Murray the hotel accommodation, Dr. F. J. Nattrass the evening functions, and Mr. G. Grey Turner the pathological museum. As chairman of the Ladies' Executive Mrs. R. A. Bolam was responsible for the well-organised ladies' club.

During the week an exhibition of surgical instruments, drugs, foods, &c., was held in St. George's Drill Hall, St. Mary's Place. There were 82 exhibitors, and the whole was representative in a high degree of the best commercial enterprise in the medical and allied sciences. Some account of the exhibits will follow.

MANCHESTER ROYAL INFIRMARY.—During the past year 57,200 persons received treatment. The annual cost of each bed was £170, and each patient cost £3 8s. 6*d.* a week.

UNIVERSITY OF BRISTOL: POST-GRADUATE COURSES IN MEDICINE.—During the past session a series of weekly clinical demonstrations was given to post-graduate students at the hospitals which constitute the clinical school of the University of Bristol. The number of medical men who attended showed an encouraging advance on last year, and the attendances remained consistently high throughout the course. The committee in charge of post-graduate organisation is now making arrangements for courses of lectures and demonstrations which have been asked for by practitioners in Wiltshire through their British Medical Association divisions. So far it has been decided to hold these courses at Trowbridge and at Swindon, and to these centres others in the counties round Bristol will doubtless be added. Inquiries should be addressed to the Director of Post-Graduate Studies, University of Bristol.

these hospitals, as at St. Bartholomew's, at the Royal Infirmary, Manchester, and at the Radcliffe Infirmary, Oxford, the fund has hitherto been applied by the staff to such purposes as the purchase of expensive apparatus or books, and the support of young practitioners taking up special branches of work; but in other cases the fund has been divided among the staff. The practice is supported by the British Medical Association on the ground that patients sent by a public authority are in the position of paying patients and that in the fees paid for such patient the medical practitioner is entitled to share. On the other hand, the honorary staffs of some hospitals are unwilling to share in such a fund; and two distinguished physicians expressed the view that if the medical staffs came to be subsidised to any substantial extent 'the bottom would drop out of the voluntary system.' It should be remembered also that, although the services of the staff are honorary, they obtain a valuable return in the form of medical and surgical experience and the enhanced reputation which accrues to a member of the visiting staff of a great hospital. If the system of carrying a percentage to a staff fund is confined to cases where the full cost of maintenance and treatment is paid by or on behalf of the patient, not much objection can (we think) be taken to it; but any extension of the practice beyond those limits appears to us to endanger the future of the voluntary hospitals."

The disagreement was unanimous, the meeting maintaining its conviction "that the essence of the voluntary hospital system is the independent and voluntary management, and that this is in no way related to the conditions of service of the medical staff."

Paying Patients in Poor-law Hospitals.

The report on the future of Poor-law hospitals came in for both general and detailed criticism, a motion to refer back the whole question for further consideration receiving influential support. The argument to await the decision of the new health authority was countered by the urgent need for the competent medical authority to lay down a considered scheme of procedure, in view of the fact that boards of guardians all over the country, and especially in Middlesex and Lancashire, were experimenting in various degrees with a combination of infirmary and private paying hospital. The "administrative control" of the medical superintendent was accepted without too precise definition of its interpretation, boards of guardians to be educated in accepting the principle of treatment by general practitioners. The selection of district medical officer by the practitioners of the area was regarded as desirable. Finally the recommendations of the Hospitals Committee were accepted in the following form:—

1. That in those Poor-law infirmaries where there is spare accommodation and when the needs of the Poor-law patients have been met, it would be desirable that certain beds should be set aside for private patients paying a fee to be settled by the guardians; that where a general practitioner wishes to continue to treat therein patients of his own, he should be allowed to do so under the general administrative supervision of the medical superintendent, and that any of these patients should be allowed to call in a consultant from outside, the patient bearing the cost thereof.

2. That for "paying" patients admitted to infirmaries there should be an inclusive charge to cover the cost of medical supervision, maintenance, nursing, food, and medicines, within the ordinary tariff and pharmacopœia of the infirmary, the patient paying his medical attendant independently.

3. That any extra nursing and any food or medicine ordered over and above those allowed under the ordinary tariff and pharmacopœia of the infirmaries should be charged as extras to the patient.

4. That all medical attendance by private practitioners on "paying" patients in infirmaries should be under the administrative supervision of the medical superintendent of the infirmary.

5. That infirmaries, so far as practicable, should be utilised for medical education.

6. That in any hospital maintained by a local authority (including the board of guardians) for general cases, provision should be made for wards for the reception on the lines of the suggested primary health centre as outlined in the Dawson Report of private patients admitted on the recommendation of their own practitioner who should be able to attend these patients in such wards.

7. That municipal hospitals should be controlled by an ad hoc committee on which there should be a small but definite representation of the medical profession, nominated by members of the local profession.

8. It is desirable in the interests of the patients that the medical superintendent should have power in special cases (including cases of urgency) to admit or retain patients from other parishes, the guardians being empowered to recover the cost of maintenance thereof from the parish or borough in which the patient resides.

9. That to meet the need of accommodation for senile and chronic cases a part of the Poor-law institution be separated from it whenever possible, which should be formed into an infirmary dependence under the control of the medical superintendent of the infirmary.

10. That certain classes of cases—e.g., tuberculosis and certain infectious fevers not already provided for—should not be accommodated in general infirmaries, but in special hospitals arranged for this purpose.

11. That the normal method of admission to an infirmary should be on the recommendation of a general practitioner.

12. That district medical officers be selected from the private practitioners of the neighbourhood.

13. That, except for the treatment of private patients, the normal medical staff of an infirmary should be a combination of the whole-time resident staff or a part-time selected staff with part-time specialists, the last being called in by the medical superintendent as and when necessary.

Criticism of the scheme as impracticable in rural areas was met by an assurance that it was only intended as a guide to general principles, modifications to be introduced to meet local needs and requirements.

TUESDAY, JULY 19TH.

Hospital Provident Scheme for London.

On behalf of the Metropolitan Counties Branch Council Mr. W. McADAM ECCLES brought forward a motion asking for approval of the national provident scheme, drawn up by the Branch Council, for hospital and additional medical services. This scheme was described in detail by Mr. Eccles in THE LANCET of May 14th last, p. 1057. Mr. H. S. SOUTTAR said that the scheme had been called revolutionary, but it was absolutely necessary in view of the bankruptcy of the London Hospital, for example, which simply could not be carried on without some such assistance. It was the business of a nation to provide its own hospital treatment. After some discussion the meeting decided to take no attitude to the scheme for the present.

Salaries of Non-professorial Teaching Staff.

On a motion to fix minimum salaries in three grades for the medical teaching staff other than professors and their assistants, it was agreed that many teaching institutions at present had the desire, although they lacked the ability to pay adequate salaries. The case was not quite parallel with that of municipal authorities who had the rates to draw upon. There was strong pressure put on the meeting not to be too tender with college authorities, which had for years sweated their teachers, but the meeting decided that the time was not opportune for taking action.

Medico-Political Committee.

Mr. E. B. TURNER, Chairman of the Medico-Political Committee, in moving the adoption of the relevant part of the report, outlined the directions in which his committee was fighting for the interests of the practitioner. It was still the aim to obtain taxation of the doctor's motor-car on the basis not of horse-power but of annual consumption of spirit, and to get a concession for the second car. Post office medical officers were receiving the full support of the Association. The Dangerous Acts Regulations, in so far as they interfered with the practitioner's work would, he thought, fizzle out in a short time. The principle of the Whitley Council was being watched in regard to its effect in weakening the authority of the Association.

Whole-time Medical Officers and Private Practice.

A motion by Portsmouth was brought forward to the effect:—

> That the Representative Body is of opinion that men practising as whole-time officials of public [illegible] should be precluded from practice for private [illegible] same district (i.) while holding their [illegible] (ii.) for a period of five years subsequently [illegible] consent of the local medical profession.

officer next day. The method of prophylaxis is as follows: The entire penis is scrubbed with liquid soap and water for several minutes, and then washed with perchloride of mercury solution, 1–2000. If any abrasions are present, these are sprayed with peroxide of hydrogen. Two urethral injections of protargol 10 per cent.) are then given and retained for five minutes. The whole penis is then rubbed with 33 per cent. calomel ointment, which is kept on for several hours. It is stated that these measures have greatly reduced the percentage of venereal disease in the service, and that if the men report for treatment within 12 hours of contact, the danger of infection is "practically nil." Protargol is preferred to argyrol for injection as being much less irritant.

Investigations in the Planting of Medicinal Herbs.

The Bureau of Plant Industry section of the Ministry of Agriculture has for a number of years experimented in cultivation and utilisation of drug plants, and noteworthy results have recently been recorded. About 80 species of drugs and herbs are now under experimental culture on heavy clay at the Government farm, where permanent plantings are being made which will furnish material now badly needed for standardising crude drugs. One important line of inquiry is the relation of special forms of culture to the development of the active principles in medicinal plants. New strains of *Atropa belladonna* and *Digitalis purpurea* have been obtained by the bureau through breeding and selection, with greatly increased alkaloidal content and this points the way to a notable improvement in the quality of certain drugs now on the market.

Quintuplets.

The *Ellenzek* describes in its issue of April 27th a case of quintuplets. Prof. Barsony, of Budapest, gives the ratio as 1 in 700,000. The case was that of a woman, aged 41, who had previously given birth to 10 children, among them being stillborn twins. She jumped from a tramcar after the latter had started, and felt something "ruptured" inside her. Typical labour-pains developed within two hours: the woman was taken from her home to the obstetrical clinic; she was four months pregnant, and had noticed that she was unusually large, but otherwise had had no discomfort; the abdomen was greatly distended, the uterus almost reaching the ensiform process. Neither the small nor the large parts of the fœtus were palpable. The os had disappeared at the time of the examination; two fœtuses were delivered within two hours. The woman had very severe pains, so that narcosis was considered, but the fœtuses were born before its induction could be begun; they weighed something over 1000 grammes together. After two weeks three other children were born, weighing about 2300 grammes. The placenta of the first two fœtuses was quite separate from the second: after the first delivery there was little hæmorrhage. After the second delivery the woman bled freely, and for two hours auto-transfusion and other life-saving measures had to be adopted. Nevertheless the puerperium was undisturbed and after three weeks the woman left the clinic as healthy as ever.

A Case of Cantharides Poisoning.

A spinster, aged 33 years, previously healthy, was taken suddenly ill with sickness and faintness, pain in the stomach, back, and intestines, and intense thirst, after taking powder made from the dried skin of cantharides, to produce miscarriage. She also confessed to having passed a catheter into the uterus and having taken very strong aperient pills containing aloes. The miscarriage took place two days afterwards, and the patient died on the fourth day of the illness. The symptoms, observed by the attending physician in the hospital, were as follows: The whole surface of the body was reddish-bronze coloured, with a dark, almost black, patch extending across the bridge of the nose on to both cheeks. The finger-tips were blue, as also the mucous surfaces of the mouth. The urine was retained, pulse 116–128, conjunctivæ tinted yellowish-brown, pupils contracted to a needle-point. From the urine, taken post-mortem, cantharidin was obtained. On her deathbed the patient confessed that she made her living by selling cantharides to women who wanted to produce miscarriage. Knowing its danger she supplied very small doses; but she herself took five times as much as she was in the habit of giving to her clients.

July 12th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Revision of French Sanitary Law.

AT a recent meeting of the Académie de Médecine Mr. Léon Bernard, the chairman of the committee appointed to advise on the revision of the French Medical Act of 1902, read the conclusions arrived at by this committee. The report proposed that public health administration should no longer remain under the supervision of local authorities, but that sanitary regulations should be under the direct management of medical officers of health under the immediate control of the Ministry of Health. To this end it is proposed that French territory should be divided into sanitary districts under medical officers of health, these districts being grouped in sanitary regions under the control of medical sanitary inspectors. The districts are to be of small radius, so that medical officers of health should remain in close contact with the people, and, on the other hand, there are to be only a few sanitary regions, of which the heads should be medical officers of health with extensive knowledge and great technical capacity. Paris and a few large cities would retain a municipal sanitary organisation, but it would be under the control of a regional inspector. The report also recommends that communicable diseases should be reported to medical officers of health directly, this declaration being made compulsory and applying to the heads of all families concerned and to the management of various establishments. It is also proposed that revaccination against small-pox should be compulsory in the course of the seventh, thirteenth, and twentieth years. Other sanitary problems, such as the disposal of sewage and the water-supply, are dealt with; with regard to shellfish, it is pointed out that further powers are required to prevent danger to health from the consumption of shellfish which have been grown and fattened in polluted water. All the conclusions of the committee were adopted by the Academy, and it was decided that the documents should be presented to the Government, at whose request the committee was formed.

Removal and Disposal of Dry Refuse.

The removal and disposal of domestic dry refuse is one of the sanitary problems recently discussed at the Société de Médecine et de Génie Sanitaire. Mr. M. Mazerolle discussed the possibility of burning the greater part of dry refuse in destructor furnaces which could be erected in houses in the future. He pointed out the advantages of compulsory sorting of the refuse in all houses, and said that at Charlottenburg there are three receptacles in every home to collect dry refuse. Two are galvanised iron receptacles with well-fitting metallic covers, the third is a cloth bag. In the latter are placed waste paper, pieces of cardboard, broken parts of crockery; in one of the metallic receptacles are thrown kitchen refuse, and in the other ashes are placed. As far as the removal of dry refuse is concerned, Mr. Mazerolle pointed out the advantages of night collection. This would be possible in Paris where most houses consist of flats, and porters have to carry out the dustbins. He also emphasised the desirability of using covered lorries; this reform is hindered in Paris by the contracts existing between the municipal authorities and syndicates of hand-sort workers who are privileged to collect dry refuse in the several quarters.

the toast of the British Medical Association, which he did in a speech of weighty content with an amusing setting. The medical man, he indicated, wrested Nature's secrets from her and made them known to the whole world, but his patient's confidences should be inviolable. Whatever sanctity attached to the confessional attached also to the consulting room, and greater even than the attainment of justice he held to be the maintenance of confidence between man and man.

Dr. BOLAM, in responding, said there was a feeling throughout the land that the time had come when the common law, based as it was on precedent and custom, must stand aside, or the medical man could not carry on his work with the true and complete confidence of the community. Dr. T. W. H. GARSTANG proposed the health of the guests, Sir THEODORE MORISON replying, and Sir HUMPHRY ROLLESTON toasted the President, Prof. Drummond, who in his reply paid a well-earned tribute to the labours of Mr. Willan, F.R.C.S., the local medical secretary of the gathering. During the dinner the wives and daughters of members were entertained by the Ladies' Executive Committee, of which Mrs. Bolam was chairman.

The dinner was followed by a dance in the King's Hall of the Armstrong College, a beautiful room for a social function, and some 250 guests worked through a serious programme of valses, fox-trots, and one-steps.

Civic and other Receptions.

The Lord Mayor entertained the President and a number of office-bearers of the Association to dinner at the Mansion House on Monday, July 18th. Sir CLIFFORD ALLBUTT, who replied to the toast of the Association, recalled that it was Newcastle, in 1870, which first offered civic hospitality to the Association. Medical men, he said, living more or less separated, were apt to get a little angular and individualistic. The Association had done much to bring them together, to compromise their various views, and to work together in mutual coöperation.

On Wednesday afternoon, July 20th, Councillor T. W. Rowe, Lord Mayor of Newcastle, entertained more than 1000 guests in the beautiful municipal gardens of Jesmond Dene. The Sheriff, Councillor Anthony Cates, was also entertaining, and the local dignitaries included the Bishop of Newcastle and the Spanish Consul. The weather, as throughout the meeting, left nothing to be desired, and the occasion was one of unaffected gaiety, to which St. Hilda's Band and the Folk Dancing Society materially added.

Dr. and Mrs. Eustace Hill welcomed 700 guests on behalf of the North of England Branch of the Association at the Hancock Natural History Museum on the same evening. The entertainment included the Elswick Works orchestra and admirable part singing by the Wallsend Male Voice Choir. The evening was reminiscent of the famous reception at the South Kensington Natural History Museum on the occasion of the last International Congress of Medicine. The Hancock Museum is renowned for the skill and artistic sense with which its birds are mounted, and in this respect, as well as in the possession of a Great Auk fledgling, the collection is unrivalled. Its able curator, Mr. Leonard Gill, was there to demonstrate the attractions.

Dr. and Mrs. R. P. Ranken Lyle gave a garden party to the ladies accompanying the representatives on Saturday afternoon, July 16th, when many tennis courts and croquet lawns were placed at the disposal of the guests.

Religious Services.

On Tuesday, July 19th, at 5 P.M., officers and members of the Association, in academic dress, attended divine service at St. Nicholas's Cathedral. Canon G. E. Newsom, vicar of Newcastle. conducted the service, the lesson being read by Rev. W. J. Jack, hon. secretary of the Free Church Council, an address being given by Dr. H. L. Wild, Bishop of Newcastle, who outlined the history of medical science from the middle of the sixteenth century on. So far, he said, as profitable knowledge went, large sections of our population, not especially of any one class, might as well be living in the dark ages. He would like to see the removal of prevailing ignorance become the concern of the whole medical profession, and he would particularly welcome addresses to the young by medical men and women of faith and vision on the use and abuse of body and mind.

Members of the Guild of St. Luke, St. Cosmas and St. Damian attended special mass at St. Mary's Cathedral, Newcastle, on the morning of Thursday. July 21st, when Father Elrington, D.Sc., set out in his address how a doctor can be a minister to the spiritual as well as to the physical needs of humanity.

Sunday Addresses on Temperance and Public Health.

A number of medical men attending the meeting took the opportunity on Sunday, July 17th, of dealing in public with various aspects of the alcohol question. At the West End Brotherhood Dr. E. R. Fothergill, of Brighton, gave an address on "Alcohol as a Beverage in Relation to Present Social Problems." Public opinion needed to be Christianised and then concentrated on social problems, when a solution for national alcoholic vice would be found. Dr. Mary Sturge, of Birmingham, spoke to a P.S.A. gathering at the Central Hall of the danger to offspring of alcoholism in the parents. It should, she thought, be part of the education of young men and women contemplating matrimony to go round the idiot asylums and see the large amount of mental deficiency attributable to parental excess. At the Byker Brotherhood Dr. Horace Rose, of Aylesbury, warned his hearers that the excesses of youth were a draft upon middle age. Speaking from 25 years' medical experience he had never known alcohol to be of any use to anyone at any time. Dr. F. C. Coley, of Newcastle, addressed the Felling Brotherhood on "Delusions about Drink." To stop the manufacture of alcohol for beverages would, he believed, do more to combat tuberculosis than the work of all the sanatoriums. At the Bentham Brotherhood Dr. W. L. Reid, of Glasgow, referred to medicated wines as an insidious and dangerous form of alcohol.

Sir Thomas Oliver, at the Chester-le-Street Brotherhood, speaking on "Success *v.* Failure," suggested that the avoidance of the wine cup tended to the creation of reliable citizens. Mr. W. McAdam Eccles at the Friends' School, Pilgrim-street, reminded his hearers that all human beings were born teetotallers, and Dr. F. B. Rutter. of Mere, Wilts, exhibited instructive diagrams and charts. Mr. Eccles gave another address later in the day at the Brunswick Chapel entitled "Great Facts concerning Alcohol." Dr. Courtenay Weeks gave an address on "Alcohol and National Efficiency" at St. Nicholas's Cathedral to a congregation which included the annual church parade of ambulance and nursing units of the St. John Brigade, and dealt with the immeasurable amount of damaged child-life directly due to drink. Dr. George Morgan, of Brighton, also spoke on "Alcohol and the Child" at the Willington Quay Brotherhood. The cumulative effect of all this teaching from medical men, with intimate first-hand knowledge of what they were speaking about must have been considerable.

Dr. George Jessel, of Southport, gave two addresses on Sunday, July 17th.; in the morning at the Church of the Divine Unity, in the evening at the Unitarian Church. Ignorance was at the bottom of much ill-health, and there was a great need for a well-organised and persistent campaign to inculcate the laws of health. The rich, he said, were as ignorant in this respect as the poor, but whereas the former could afford to pay for their mistakes, the latter not only suffered grievously themselves, but became a charge upon the rest of the community. Organised religious bodies had a direct interest in supporting health measures, especially on the educational and moral side. We needed, however, to get away from the idea that there was a monopoly in spiritual insight.

"Audi alteram partem."

SMALL-POX IN NOTTINGHAM.

To the Editor of The Lancet.

Sir,—Our first case of small-pox this year occurred in February (R., Feb. 16th), and here, I think, the infection was imported from a Northern town. There was no causal relation between this case and those of the current outbreak. I am now endeavouring to construct, historically, the relation of the earlier cases of this local outbreak to one another, but the task is laborious and difficult, because at least seven of them were dealt with by their medical attendants as cases of varicella; and even now, notwithstanding fairly palpable evidence of recent small-pox in the pitted and pigmented scars on face, wrists, and hands of several of these, I have not been able to obtain much assistance in my search for them. I am inclined to think that this last outbreak of ours had origin either in the Long Eaton cases or in the sources from which these latter derived their infection—i.e., I believe, cases imported from abroad. The dates of onset in the two groups appear to fit; Long Eaton, like Nottingham, is a lace and hosiery centre; the towns are only seven miles apart and do much business together; and the communication by road and rail between the two places is very free.

The earliest cases of the current outbreak which I have been able to discover up to the present date from the first week of May. The total number of earlier cases hitherto brought to light which ran their course without a correct diagnosis is seven, but there are many reasons for thinking we have not found them all. There are 15 cases of recent origin (7 commencing last week and 5 the week before) now in the City Small-pox Hospital on Bulwell Forest. Most of the patients (all but 3) are unvaccinated, most of them have fairly severe, unmodified small-pox, but two have the milder attenuated form of which we have lately heard so much. There has been no fatality up to the present, nor, I think, is a fatal issue to be anticipated in any of those at present in our charge.

There are many cases of chicken-pox in this district, and some of these are exceptionally severe. One case which I saw with Dr. R. Heelis (of Lenton) on July 21st had an early temperature, I believe, of above 105·5° F., and although there is no difficulty for medical people with much experience of small-pox in distinguishing between severe typical examples of the two diseases, I think the severity of many of the local varicella cases explains in some measure the large number of mistakes which have recently been made by practitioners who are lacking in knowledge of the former disease.—I am, Sir, yours faithfully,

Philip Boobbyer,
Medical Officer of Health.

Health Department, Guildhall, Nottingham,
July 25th, 1921.

DIGITALIS AND THE PERIPHERAL CIRCULATION.

To the Editor of The Lancet.

Sir,—I cannot agree with Dr. W. J. Grant that I have not accurately defined the issue of this discussion. It is more correct, I think, to say that he has shifted his ground, though this is of little import.

He agrees "that an increased flow per time unit can be obtained through the arterial system in the presence of lowered blood pressure, *provided there is vaso-dilatation.*" If there is no vaso-dilatation then "the arterial passages and exits *remain as before.*" The result is that "effective *resistance* is offered . . . by the . . . undilating vessels and the intra-arterial pressure rises." Is dilatation of the vessels the only method of lowering the resistance, as your correspondent asserts? Does not a diminution of the total quantity of fluid in an "undilatable" vessel have the same effect in regard to lowering resistance as dilatation? That is precisely what takes place under digitalis. We have seen during diastole the quantity of blood is less than normal; indeed, the main conclusion of my paper is that in the whole peripheral circulation the quantity of fluid is less than normal. The statement that if there is no dilatation "the arterial passages and exits remain as before" is not correct. Your correspondent is not able to discern such a simple truth staring him in the face. We may have an increased flow per time unit in the vessels under a lower systolic pressure if the resistance is diminished. The main conclusion of my paper is that the resistance cannot be otherwise than diminished in the circumstances. It is not necessary to suspend the physical laws from operating to make my conclusions possible. All that is necessary is to suspend the blunders of your correspondent and the whole matter becomes quite plain. Had Dr. Grant thought out the problem, I do not think the controversy would have arisen, and I regret that he did not state his reasons why an increased pressure in the veins is necessary in order to obtain a rise in the intra-arterial pressure.

Once it is admitted that digitalis effects an increased output, apart from other considerations (and there are few who will dispute this) the main conclusion arrived at in my paper follows from it with mathematical certainty. The total volume of blood in the circulation is fixed; a greater output per given time means increased velocity through the peripheral circulation; since during the systole the flow of blood takes place at much greater speed than the diastole, hence the more powerful the systole the greater the velocity of the total volume of fluid. This is as obvious as the fact that an augmented output of the heart entails an increased intake. The elucidation of this fact ought to be of considerable practical value. A quicker turnover of a medium such as blood, whose function it is to provide nutriment and remove the waste products of the tissues, would not only effect an improvement in turn of the heart muscle, but also of any other organ which suffers from malnutrition, brought about by no matter what cause.

Even if the systolic pressure is not increased by digitalis, the increase in pulse pressure cannot be indifferent in cases of high degree of arterio-sclerosis. It is held by some that arterio-sclerosis, which often manifests itself at an early age in cases of aortic regurgitation (even without a history of syphilis) is due to the strain the vessels have to bear, owing to the high pulse pressure which is a usual feature of this disease. I am, Sir, yours faithfully,

Liverpool, July 25th, 1921. I. Harris.

THE USE OF RHUBARB IN ACUTE BACILLARY DYSENTERY.

To the Editor of The Lancet.

Sir,—For the last three years we in Nairobi have been treating acute bacillary dysentery with powdered Turkey rhubarb root (pulv. rhei rad.). The dose is, roughly, half a teaspoonful every one, two, or three hours until the rhubarb appears in the stools. Then slacken off (the use of cachets is handy as there is less chance of vomiting). The stools will then become copious, the bad smell, mucus, and blood will disappear, so also will the colic, straining, tenderness on pressure, fever, rigors, dry tongue, fast pulse, and all the other signs and symptoms of the acute general poisoning of this disease. In children give small doses often, mixed with treacle (say, in a child of 5, give gr. v. every two hours for six hours). In them stop, after about half a dozen small doses, without waiting for the rhubarb to appear in the stools, as in some children there is apparently a sudden accumulative effect and then the most obstinate diarrhœa may follow, although the dysentery is cured. In adults the rhubarb will usually appear in the stools within six hours—in children very much longer—so

KING GEORGE'S SANATORIUM FOR SEAMEN.

THE Seamen's Hospital Society has, during its century of existence, done great things for the sick sailor, and to its other benefits, helped by the enterprise of Lord Inchcape, has now added a splendid sanatorium for the tuberculous, well planned and situated in lovely grounds at Bramshott in Hampshire. The menace of tubercle to the merchant marine is dire. In the last statistics on the deaths of seamen published by the Board of Trade, covering the year ending June 30th, 1914, there are shown deaths by tuberculosis as under:—

1913-1914.	Lascars.	Foreigners.	British.	Total.
	45,571	29,699	170,439	245,619
Deaths from tubercle				
General	3	1	2	6
Pulmonary ..	26	16	22	64
Total	29	17	24	70
Death-rate per 1000	*0·64*	*0·57*	*0·14*	*0·28*

These figures give us death-rates only; there are no statistics of illness. The only other statistics of illness in the merchant marine available are those so valuable presented to the Royal Society of Medicine by Dr. Arnold Chaplin from his 16 years' experience in the Eastern trade, in which the Lascar death-rate from tubercle was stated as 0·47, and the European death-rate as 0·14 per 1000, figures very similar to those given above. Dr. Chaplin gave the attack-rate as 5 per 1000 for Lascars, 2 per 1000 for Europeans; and those figures suggest that for each death shown about 12 cases occur (10 Lascar, 14 European). The statistics of health of the Royal Navy suggest a very similar position.

We may assume, then, that for 70 deaths from tuberculosis in the merchant marine there are probably upwards of 700 cases of the disease afloat in the ships. How far it will be possible to deal with these patients under the National Health Insurance we cannot yet say. Complaints are being made in certain quarters that the seamen's contributions are at present being in great measure lost. But, at any rate, a start has been made towards coping with the problem by the Seamen's Hospital Society. The new sanatorium at Bramshott, which was opened on July 12th by the Duke of York, is called King George's Sanatorium for Sailors; it is built on a property of 100 acres, some of which is at present let. A house already on the property has been made into a nurses' home, and in the sanatorium itself accommodation is now available for 80 cases and is arranged in a crescent facing south, in two stories, with two ten-bed wards at each end; single and double cubicles fill in the space between these wards. Furniture is reduced to a minimum; all corners are rounded, the floors are "jointless," the southern side of the cubicles is all glass, and the casements open conveniently. Certainly the patients are fortunate in their surroundings; an extensive lawn, magnificent trees, and a dry soil, with shelter from all violent winds, give them every opportunity for recovery. As money increases further crescentic sections will be opened on the ground already owned. At present two more are in prospect, which will make it possible to receive 240 patients. The few cases already transferred are being treated by a physician who is in practice near by, but it is intended shortly to appoint a resident physician and superintendent; the matron and nurses are already in occupation. A recreation room for the patients is to be constructed; gardening and other trades will be taught, a carpenter's shop being already prepared. It will be seen that the sanatorium is being directed on wise lines, and, as the Duke of York said in his opening address, any who feel gratitude to sailors for their work in the war may well give that gratitude expression by sending a subscription to King George's Sanatorium for Seamen, Bramshott Manor, Hants.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Children and Milk-borne Diseases.

THE statistical bureau of Budapest has just issued its annual report for 1920, in which it is stated that notwithstanding unusually prolonged periods of intensely hot weather, there were fewer deaths of children under 5 years than in any preceding summer; for the first time in the history of the city the summer mortality fell below 50 per 1000 per annum. The Committee for Distribution and Supply of Pure Milk to Babies undertook the supply of pasteurised milk in 1906; 2112 children under 5 years died in the summer of that year. In 1920 there were only 1710 deaths in a population of children larger by 45,000 than that of 1906. The Committee are convinced that pasteurisation of milk supplies of the cities and towns, under careful supervision of medical officers, would still further reduce the death-rate.

Myopia in School-children.

Dr. Bogdan, in his account of the examination of 200 text-books from a hygienic point of view, draws particular attention to the fact, already established by many prominent investigators, that myopia in children either originates from or develops in the schoolroom. The chief cause is the too prolonged reading, writing, and drawing; undue strain of the muscles of accommodation causes an active hyperæmia; the venous circulation is hindered, there is an increase in intra-ocular pressure, and the sclerotic is gradually stretched. Too strong convergence works even greater harm. It is, of course, understood that in some children near-sightedness is hereditary, and, as a result they become affected more quickly than their healthier comrades. Near-sightedness may also be the result of insufficient light and improper equipment in desks and other school furniture. Dr. Bogdan insists that paper used in text-books should not have a glossy surface. Under artificial light a glossy surface causes improper focussing of the eye and necessitates frequent changes in the position of the book as well as of the head. The paper should be thick enough to prevent the print on one page from penetrating to another. A few authorities have recommended yellow paper, but the majority favour white paper, which gives a sharper contrast between the printed matter and the background.

Simultaneous Occurrence of Syphilis and Tabes.

Dr. Frey, lecturer on nervous diseases, stated his conclusion from a large number of recorded cases, that with pronounced tabes the syphilitic virus may still continue active within the body, hence a combination of manifest syphilis of the skin or internal organs with typical tabes is not a very rare occurrence. It seems that syphilitic spinal meningitis is particularly common. With later occurrence of tabetic symptoms, active syphilis is less common, as observed by Adrian in Germany. The combination is more frequent in the male sex, in which syphilis is oftener encountered and the disposition to posterior degeneration greater. Tabes appears later in the majority of cases than tertiary lues; thus a somewhat more favourable prognosis may be made where both conditions are combined, since the process may often be arrested by active antisyphilitic treatment.

Venereal Prophylaxis.

Dr. Lükö has reported the results of venereal prophylaxis, as carried out in the Hungarian Army. All men who have exposed themselves to the risk of venereal infection have to report to the medical

The following awards were also made:—*Faculty of Medicine.*—Thesis Gold Medal: Joseph G. Greenfield. Cameron Prize in Practical Therapeutics: Jules Jean Baptiste Vincent Bordet. Goodsir Memorial Fellowship: Robert Kho Seng Lim. Straits Settlements Gold Medal: Francis H. Stewart. Gunning Victoria Jubilee Prize in Medicine: Robert L. Impey. Gunning Victoria Jubilee Prize in Anatomy: Claude W. Stump. Ettles Scholarship and Leslie Gold Medal: Alexander L. M'Gregor. Allan Fellowship in Clinical Medicine and Clinical Surgery: James I. M'Can. Murchison Memorial Scholarship in Clinical Medicine: Jessie M'Cririe Craig. M'Cosh Graduate's and Medical Bursaries: Edward A. Wilson. Beaney Prize in Anatomy and Surgery: Alexander L. M'Gregor. Mouat Scholarship in the Practice of Physic: Robert G. M'Intyre. Conan Doyle Prize: Alexander L. M'Gregor. Annandale Gold Medal in Clinical Surgery: Edward A. Carmichael. Buchanan Scholarship in Gynecology: George J. Alexander. James Scott Scholarship in Midwifery: Isobel M. Finlayson. Scottish Association for Medical Education of Women Prize: Isobel M. Finlayson. Dorothy Gilfillan Memorial Prize: Jessie M'Cririe Craig. Wellcome Medals in the History of Medicine: Gold Medal, James M. Anderson; Silver Medal, Thomas Ferguson. Pattison Prize in Clinical Surgery: Donald S. Middleton and Arthur J. Wilson (equal). Wightman Prize in Clinical Medicine: Arthur J. Wilson. Cunningham Memorial Medal and Prize in Anatomy: Donald G. S. M'Lachlan. Whiteside Bruce Bursary: Donald Mainland.

University of Aberdeen.—The summer graduation ceremony was held on July 14th, when the following degrees were conferred:—

Doctor of Medicine.

*John Kirton, *George F. Mitchell, and Alexander J. Will.

*Commendation for Thesis.

Bachelor of Medicine and Bachelor of Surgery.

*Cuthbert A. Allan, Allan B. Clark, Robert Dawson, Douglas R. Dugan, Frances M. Duguid, Lewis I. Duncan, Margaret F. Fraser, Barbara M. Geddes, James W. Gill, Ethel E. Gray, Charles Joiner, Patricia Henderson Low or Cassie, *Elsie J. Mann (second-class honours), *Max Mindé, Frederic H. Mollière, Ronald M. Savege, Elsie J. Scorgie, Jenny H. A. Simpson, Frances M. G. Sinclair, †Annie Thain (first-class honours), *George Otto Thornton (second-class honours), Elizabeth M. Walker, Nora I. Wattie, and Fred Wilson.

* Completed Final Professional Examination with distinction.
† Completed Final Professional Examination with much distinction.

The John Murray Medal and Scholarship and the Lyon Prize were awarded to Annie Thain.

Diploma in Public Health.

Emily M. Badenoch, Charles A. Harvey, Frederic D. R. Keyt, Winifred M. A. Kindness, Mathilda F. Menzies, and Daniel I. Walker.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.—The following candidates have passed the Triple Qualification Examination:—

Third Examination.

James M. Crombie, Matthew Burn, Andrew A. Dewar, Helen J. Hamilton, John J. Mann, George F. Maher, Robert P. Anderson, Thomas P. Bremner, William Paris, Thomas E. Mathias, Charles W. de Villiers-Pritchard, William H. Griffith, Israel Rostowsky, Albert R. Rellum, Richard F. Kerr, and Elizabeth Clark.

Pathology.—David R. Paterson, Wilhelmina C. Storrie, Herbert Chorley, Johannes Jacobus Malan, and Owain ap Vychan Jones.

Materia Medica.—Montague A. Watson, Leonard A. Watson, Donald Jack, Jemima M. McKendrick, Charles C. Robson, George H. Tarras, Edward T. Hale, David Isaacs, Douglas M. Beaton, Samuel I. T. Wills, James H. Murrell, and Alexander L. Tinto.

Final Examination.

William B. Stott, Edward S. Godlieb, Otho P. Fox, John H. Bain, Vincent H. L. Anthonisz, Robert E. O'Keeffe, James S. A. Rogers, Ram Nath Nanda, Abdus Shakur, Hubert E. C. Cezair, James Pedris, Alexander G. Thom, Aflatun Yacub Khan, Emanuel J. Swirsky, James McNie Campbell, David M. Scrimgeour, Reuben Abramsky, Jane Copes, Eric W. Johnson, John Connal, John K. Holmes, Herbert Brown, Alan W. Hart, Hugh McKerlie, Gwilym ap Vychan Jones, and Elliot P. Dewar.

Medicine.—Lionel R. Bergson, Frank Walwyn, Herbert W. Amyes, Robert R. Waters, Albert R. Rellum, Henry P. Samuel, and Vadakath Padmanabha Menon.

Surgery.—Jatindra Kumar Sen, Herbert W. Amyes, Leo H. Peries, John Hagard, and Vadakath Padmanabha Menon.

Midwifery.—John G. Collee, Frank Walwyn, Robert R. Waters, Henry P. Samuel, and John Hagard.

Medical Jurisprudence.—Robert W. P. Hall, Gabriel G. King, Ian B. Cummings, Alexander W. Buchan, James B. Hendry, James S. Allan, John M. Cockburn, William L. Murray, Henry G. F. Cubitt, Herbert W. Amyes, Andrus M. Samarasinghe, Salomon Asam Ho Asjoe, Arthur S. Wickremesinghe, Frederick P. Lisboa-Pinto, Albert R. Rellum, and Jemima M. McKechnie Calder.

Royal College of Surgeons of Edinburgh.—*Presentation of Portrait of Lord Lister.*—At an extraordinary meeting of the College, Dr. George Mackay, the President, presented to the College a portrait of the late Lord Lister. The picture is a full-sized copy made by Mr. Dorfield Hardy of the portrait painted by W. W. Ouless, R. A., in the possession of the Royal College of Surgeons of England. In accepting the portrait on behalf of the College, Dr. McKenzie Johnston, the Vice-President, expressed the satisfaction the College had in acquiring this memorial of its most distinguished Fellow through the generosity of their President. Lord Lister entered upon his great surgical career as house surgeon to Prof. Syme in the old Royal Infirmary of Edinburgh. Later he acted as a lecturer on surgery in the extra-mural school in connexion with the Surgeons' Hall and as assistant surgeon to the Royal Infirmary, and subsequently he succeeded Syme in the chair of Clinical Surgery in the University. He became a Fellow of the College in 1855, and on the occasion of the celebration of the fourth centenary of the College in 1905 was elected an Honorary Fellow.

At a meeting of the College held on July 19th the following successful candidates, who passed the requisite examinations between March 21st and 25th, were admitted Fellows:

Alfred D. E. Bayliss, Keith P. Brown, Robert S. J. Fitzgerald, Andrew Fowler, William J. Grant, Daniel F. Hegarty, Archibald Langwill, John J. Liston, James S. Robinson, John J. McIntosh Shaw, Richard W. Smith, Quintin Stewart, William R. Stewart, and Peter P. Wright.

General Infirmary at Leeds.—Changes in the chairmanship of the infirmary have not been of frequent occurrence. Mr. Benson Jowitt held this office for 20 years, and his successor, Mr. Charles Lupton, has just retired also at the end of 20 years' service. Mr. Lupton's term of office will long be remembered by the public of Leeds and especially by the members of the honorary staff of the institution. Under his care and direction many improvements have been carried out. Among these may be mentioned the extension which has just been completed, in memory of the late King Edward. The Prince of Wales had expressed his intention of spending some time during his visit to the Yorkshire Agricultural Show in inspecting the infirmary, and had consented to open the extension; the postponement of his visit is only a less reason for regret than its cause. The extension comprised a new out-patient department, a new suite of general and of special operating theatres, and a new ward-pavilion, which have for some months been in full occupation. The question of accommodation for children had to be considered; there has never been any separate hospital for children in Leeds, and three of the large wards are to be allocated for the reception of children. Apart from the cots for children in these wards and in the semi-open-air ward which is to be provided on the terrace—which will together provide accommodation for about 120 children—it was found that there would be in the infirmary 432 beds for adults. The numbers allotted to the various departments will be as follows:—Medical, 113 (66 male and 47 female); surgical, 206 (135 male and 71 female); ophthalmic, 44 (27 male and 17 female); aural, 26 (14 male and 12 female); gynæcological, 23; isolation

A NEW INCOME-TAX RULE.

AT a late stage in the proceedings on the Finance Bill the Chancellor of the Exchequer moved a new clause which may be of special importance to many members of the medical profession. It relates to the proportion of the rent or annual value of the dwelling house which may be charged as a deduction in bringing out annual profits. At present the rule is that, when the same premises are used for both residential and professional purposes, there shall be charged as expenses of the practice only such part of the rent (if the doctor is a tenant) or annual value (if he is proprietor) as corresponds to the part of the premises used for professional purposes, and then the present rule proceeds —

Provided that where any such part is so used, the sum so deducted shall be such as may be determined by the Commissioners of Inland Revenue, *and shall not exceed two-thirds of the annual value or of the rent bona fide paid for the said dwelling house or offices.*

The change now made for the current year, as from April 6th last, is that the above restriction of a maximum of two-thirds is qualified as follows :—

Unless in any particular case the Commissioners are of opinion that, having regard to all the circumstances, some greater sum ought to be deducted.

It was strongly argued that many medical men were very hardly and unfairly hit by the two-thirds limit, when they were practically compelled by the nature of their practices to reside in expensive neighbourhoods, where they would never have installed themselves except for professional reasons. Thus it might easily result that to leave them domestically burdened with even one-third of the rent or annual value and rates was excessive and unfair. It is not quite clear, but it is at least maintainable, that such cases will obtain relief under the new rule. It may be said that unless the part of the house which is used for the practice represents more than two-thirds of the total annual value, no more than two-thirds can even now be passed as a deduction. But cases such as we have referred to are at least within the spirit of the new rule, and our readers would be well advised to act on that view in any case where the circumstances afford a basis for it.

Apart from these considerations two other points may be noted: 1. Where the house really serves three purposes—residence, practice, and private nursing home—the new rule will apply in terms. 2. The part devoted to the practice may not be two-thirds of the size of the house, and yet more than two-thirds of its annual value.

MEDICAL AND DENTAL TREATMENT OF SCHOOL CHILDREN.

HAVING ascertained that the total amount collected from parents during the year 1919–20 for medical and dental treatment of school children was only £4344, against a total expenditure on this work of £103,140, the London County Council has decided to vary its scale of charges. The unsatisfactoriness of the present position is accentuated by the fact that, quite apart from the actual cost of administering treatment, the mere collection of the £4344 cost the Council no less than £6225. The Education Committee of the Council is of opinion that if parents can afford to pay the full cost of treatment at the Council's centres there is no justification for charging less. At present parents are not permitted to pay the full cost, and any voluntary offer to do so has been refused. Henceforward those parents who, though unable to pay the fees of a private practitioner, are willing to pay to the Council the full cost of medical or dental treatment of their children, shall be enabled to do so.

The charges hitherto in force were 1s. for each period of six months for dental treatment and medical treatment of major ailments, and 3*d.* instead of 1s. for minor ailments. The new scale of charges to parents who do not pay the full cost is as follows :—

(1) *Minor Ailments.*—No charge for the first period of a fortnight; thereafter 1s. for the first period of six months, and 1s. for each subsequent period of six months.

(2) *All other cases, including dental cases*, a charge of 1s., so long as the index figure of the cost of living is more than 100 per cent. above the pre-war cost of living; when the said index figure falls to 100 per cent., or less, above the pre-war cost, the charge of 1s. shall be increased to 2s. as from the first day of the month following the publication by the Ministry of Labour of the fact that the index figure has so fallen; provided that any of the above charges may be remitted in full in respect of children whose parents have been ascertained to the satisfaction of the Children's Care (School) Committees to be necessitous.

The reason for allowing a fortnight's treatment without charge in the case of minor ailments is to ensure that small matters—trivial accidents, &c.—shall not be neglected, and that parents shall not be deterred from allowing their children to be treated. The Education Committee urges that prompt attention to minor ailments is essential, since a child's trivial complaint is frequently a symptom of something more serious.

In the course of a long debate on the Committee's proposals an attempt was made to refer the Recommendation dealing with the new scale of charges back to the Committee, on the ground that it was unreasonable to increase the charge from 1s. to 2s. when the index figure of the cost of living fell below 100 per cent. When this point was reached the wages of the workers, it was argued, would also fall, and parents would find it still more difficult to pay even the shilling now exacted. The motion was defeated.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. A. La T. Darley is placed on the Retd. List at own request.

Surg. Comdr. W. B. Macleod is placed on the Retd. List with the rank of Surg. Capt.

Surg. Lieut.-Comdr. F. C. Alton withdraws with gratuity.

Surg. Lieuts. to be Surg. Lieut.-Comdrs.: J. F. M. Campbell, R. J. Inman, and R. Lyon.

ROYAL ARMY MEDICAL CORPS.

Maj. W. E. Marshall is secd. for Foreign Office service.

Capt. W. W. MacNaught retires, receiving a gratuity.

Capt. W. V. Corbett retires, receiving a gratuity, and is granted the rank of Maj.

Temp. Capt. B. H. Woodyatt relinquishes his commn. and is granted the rank of Maj.

The undermentioned relinquish their commns. and retain the rank of Capt.: Capt. S. P. Snook, on account of ill-health; Temp. Capts. J. B. Morrison and J. MacRae.

I. Ridge-Jones, late temp. Capt., to be temp. Capt.

ARMY DENTAL CORPS.

Temp. Capt. W. M. Ferguson, Dental Surg., from Spec. List, to be Capt.

Temp. Capt. J. Marron, Dental Surg., from Spec. List, to be Lt.

Flight Lt. Lawrence Somerville-Woodiwis, from R.A.F., Dental Branch, to be Lt.

TERRITORIAL FORCE.

Maj. J. Taylor (late R.A.M.C.) to be Capt., and relinquishes the rank of Maj.

Maj. G. Dalziel (late R.A.M.C., Spec. Res.) to be Capt., and relinquishes the rank of Maj.

Capts. (late Capts., R.A.M.C.) to be Capts.: F. L. Napier, R. F. Young, J. K. Rennie, and J. O. Thomas.

Capt. M. D. Mackenzie (late R.A.M.C.) to be Lt., and relinquishes the rank of Capt.

TERRITORIAL FORCE RESERVE.

Col. Sir H. A. Ballance resigns his commn. and retains the rank of Col.

MESOPOTAMIA HONOURS.

The King has given orders for the following appointments to the Most Excellent Order of the British Empire for services in Mesopotamia:—To be Officers of the Civil Division: Mr. G. N. Braham, Surgeon Specialist, Baghdad, and Mr. A. H. Hall, Civil Surgeon, Diwaniyah. To be Members of the Civil Division: Asst. Surg. H. C. Berlie, Medical Officer, Bandar Abbas, and Miss Elizabeth Alice Emuss, Matron, Civil Officers Hospital.

not be possible at present without an amendment of the law. He could not believe that when the changed conditions of medical and surgical treatment were considered the Ministry of Health would be satisfied to leave the hospitals without a large contribution from the great surpluses now being accumulated, and which had already been accumulated by the Societies. During the war the vast bulk of the people, and especially those who enlisted in the forces, came to demand a higher standard of medical treatment, and received it. They were not willing to revert to the old order, and were not satisfied now merely with the panel doctor, not at his best, but at his worst. They frequented the out-patient departments of the hospitals in greater numbers than they did, and even though in some cases they had to pay a small fee the insurance fund had benefited materially by the lessons of the war.

Hospitals as Training Schools.

It was forgotten sometimes that at least the 12 general hospitals in the London area, which had schools attached, were doing a great deal of work which was in no sense confined to the sick poor either in their own area or even within the bounds of the metropolis. They were the training schools for the medical profession of the whole Empire. At Cambridge University, for example, they could not in the medical school there fully equip a man for the practice of medicine, because although theory could be taught, it was obvious that they had not the pathological material for the purpose. It was left to the hospitals to take upon themselves the whole of the medical research, which was increasing in importance every day. That was a matter not only of national but of imperial importance. It was freely stated and claimed that the voluntary system of our hospitals had enabled medical skill and genius to be developed so far and so fast that in those matters we were ahead of the rest of the world. If that was true it was mainly because the 12 great general hospitals of London, with others in Edinburgh and one or two of the great cities, had carried out this urgent research and experiment, and they were doing it, of course, at the expense and by the goodwill of those who subscribed to their funds. The equipment of the general practitioner throughout the country was being raised year by year by the experience of what was being done in the hospitals and by the knowledge that was imparted to him, directly thus or indirectly through the medical journals, and there was a clear case on that ground—that the hospitals should receive fair payment out of the great surpluses of the Approved Societies.

Relation of Poor-law to Voluntary Hospitals.

The second point on which he asked for further investigation was the relation of the Poor-law institutions to the voluntary hospitals. If nothing more was done, and things were left until there could be a general reform of the Poor-law system—a revolution of our local administration, for that was what it meant—he thought they would have to wait a long day before any proper system of connexion or relation between the Poor-law institution and the voluntary hospital was brought about. A good deal of money for building and development might not be required if they were able to put the Poor-law infirmaries in their proper place as part of the general system of medical relief, not only in London, but elsewhere. There were 90,000 beds in the Poor-law infirmaries of the country and 20,000 in London alone. In 1920 the total number of beds in the voluntary hospitals in Great Britain was 32,191. Half of the beds in the Poor-law infirmaries were not full; half of them were never used in the year. Even when they were used there were not the consultants or the experts available as there used to be in the old days when the pauper cases were dealt with in the general hospitals. They were not available for the graver sorts of disease and major operations. The equipment was often quite inadequate for the general range of hospital work. He was sure that there could be such a coördination of activities and of capacities in regard to the care and cure of the sick poor as would set the whole system in order and prevent a large waste of public money, such as was inevitable now. If the law were so amended that they could concentrate the cases of paupers (if the Poor-law still continued its nomenclature) in a certain number of Poor-law institutions, and made the others available for the general purposes of treatment and relief, that in itself would be a great gain.

Administration of the Government Grant.

The Earl of **Onslow** (Parliamentary Secretary of the Ministry of Health) expressed the thanks of the Government to Lord Cave and his Committee for the useful and valuable suggestions contained in their Report. The British Medical Association, meeting in Newcastle, had just endorsed the recommendation that the voluntary system should be maintained. The Government most cordially agreed with that view. The noble earl went on to describe the Government scheme for carrying out the recommendations of Lord Cave's Committee, as set forth in a White Paper recently issued by the Ministry of Health. The Minister he said, had adhered to the recommendations of the Committee with regard to the constitution of the Commission appointed to administer the Government grant of £500,000 with one exception—namely, that he had added one more member to represent Wales, and he was glad to say that Lord Clwyd had accepted the position of representative of Wales on the Commission. They were hoping to get the most representative local committees they possibly could, representative of those in touch with the voluntary hospitals in any way, of the medical profession, of the hospital boards of management, of employers, of employed, of local authorities, and of women. The Government had decided that they ought not to contribute towards building schemes at present, when the hospitals were not paying their way, and the cost of building was steadily falling. In the present financial condition of the country the Government must be content to contribute only £500,000 in aid of the deficit, and rely upon the public to provide the rest. The duties of the Commission would be to deal with the situation at once, and make such advances from the fund as would enable hospitals to carry on, at any rate for the present, and relieve their most immediate wants. It was proposed that King Edward's Fund should take the place occupied by local committees in the provinces, and act as the local committee for London. The Commission and the local committees were in no way intended to exercise control over the hospitals. They were there rather to help the hospitals to rise on their legs again. The sole intention was to administer the Government grant so that the necessity for it should disappear quickly. The whole question of hospital areas and the sufficiency of beds in those areas would be a matter for the Commission and the local committees. With regard to Poor-law infirmaries there were 92,000 beds in those institutions, but they were not all in separate infirmaries; many of them were attached to workhouses. An average of 20,000 beds in them were vacant during the winter, and 30,000 in the summer. There were 36,607 beds in separate infirmaries, and on January 1st last 9150 were vacant. He did not know that they were all suitable beds, but, at any rate, they were there, and it was quite possible that the accommodation in these infirmaries might be of very great value and assistance in relieving the hospitals. The matter would be carefully investigated, and he would be disinclined to press the Commission to ask the local committees to submit proposals until they had had every opportunity of considering the matter fully and adequately, and with special regard to the resources of their areas. With regard to the question of contributions by the approved societies, it would be premature for him to say anything definite at the present moment. But the point would receive the most careful consideration, as would all matters which would tend to relieve the situation and to assist the hospitals.

Lord **Somerleyton**, as one connected with the Central Fund for Hospitals in London, said it was quite clear that the central authority for London would obviously have to take into consideration the fact that the Poor-law infirmaries were now more available for the use of hospitals than they were at the time when plans for extensions and alterations were originally put forward. This consideration would therefore require, and would no doubt receive, the most careful attention of the central authority for London.

A Wider View of Hospital Needs.

Lord **Dawson** of **Penn** said that when the Committee's recommendation of a grant of £1,000,000 for the hospitals was reduced by half they all realised that the Government had only made that reduction under the cogent pressure of financial difficulties. But, in view of that fact, he asked whether it would not be wise to reconsider the basis of its distribution. The sum of £500,000 when divided amounted to very little in an individual case. It was an important matter to put the teaching hospitals of the country into an entirely different schedule. If anything interfered with the efficiency of the teaching hospitals the whole nation suffered, because they provided not only the doctors and the nurses for the coming generation, but they set the standard of work. As a consequence the standard of work throughout the whole country could easily be so lowered in a short space of time as to deteriorate medicine in this country for 20 years. The question of the Poor-law infirmaries should not be allowed to rest longer. While they were waiting for that spare time which never came to Governments, in order to solve the Poor-law question, the country was prevented from utilising to the extent that it could the resources of Poor-law institutions. Lord Burnham had referred to the sick poor. That was not a wide enough view to take. The public were all poor now, and many of them were sick. The number who required institutional treatment steadily increased year by year, and much so that I often give some other drug afterwards to carry it along quickly. In both adults and children give lots of sod. bicarb. and potass. citrat., alternately, in plenty of water. This is most important, especially in children, as there is always great acidosis. I know of no remedy in medicine which has such a magical effect. No one who has ever used rhubarb would dream of using anything else. I hope others will try it in this dreadful tropical scourge.

I am, Sir, yours faithfully,
Nairobi, B.E.A., June 24th, 1921. R. W. BURKITT.

Obituary.

ARTHUR CHARLES OLDHAM, F.R.C.S. EDIN.,

MAJOR, R.A.M.C. (T.).

To those who knew him the news that Arthur Charles Oldham had died of sunstroke on July 21st in the neighbourhood of the Persian Gulf came as a real blow. About a year and a half ago he accepted a medical appointment at Baghdad under the War Office, and despite his having passed the age of 50, he seemed to be standing well the trial of his patriotic action. "'A.C.O.,' as he was affectionately known to his friends," writes one of them, "came of a distinguished family which is honoured in science in this country and many parts of the world. In early youth he had none of the usual advantages and was compelled to rely entirely on his own resources and efforts. Happily he was blessed with an excellent memory and a capacity to take pains with everything he undertook. He studied at Owens College, Manchester, and at the Royal College of Surgeons, Ireland, and at the latter institution in 1894 he was awarded the medals for medicine and surgery. Eventually settling in Kidderminster he obtained a large and widely extended practice. Possessing marked surgical ability and skill in diagnosis, he endeared himself to his patients of all classes. No trouble was too much for him to take, be the sufferer well-to-do or the poorest of the poor. Could any testimony be higher! As in his work so in leisure moments Oldham was a keen sportsman, a golfer above the average, and an enthusiastic student of good music and fine arts. As a Territorial officer of some standing he went on active service in August, 1914, and served throughout the war in England and France, latterly as specialist in venereal diseases.

"Being over 50 many friends regretted his decision to go out to the East, but all that knew him were certain that no risk would deter him from doing his duty. He has played his last round for his country, and it is certain he played it well to the end. Though he lies at rest 'somewhere East of Suez' the memory of an affectionate brother and kind-hearted friend will be kept green for many a long day in the hearts of those he was loved by."

ST. THOMAS'S HOSPITAL ANNUAL DINNER.—The annual Old Students' Dinner will be held on Friday, Oct. 28th, at the Wharncliffe Rooms, Hotel Great Central, Dr. H. W. G. Mackenzie in the chair. The usual notices will be sent out early in October.

UNIVERSITY OF BRISTOL APPEAL.—The University of Bristol has at length issued the appeal for adequate endowment, long deferred on account of the coal strike, in the form of a pamphlet, backed by posters displayed throughout the city. The argument of the pamphlet is that Bristol has been generous in the provision of University buildings, and that to make these effective a large increase of capital is necessary to provide for the expenses of maintenance. There is a debt of £70,000 on which interest is being paid. The sum asked for is £1,000,000, which in the opinion of the financial advisers of the University is by no means unattainable. In a list of chairs as yet without endowment are included those of Anatomy, Pathology, Medicine, Surgery, and Obstetric Medicine (the three last, indeed, are not only without endowment but almost without stipend), while that of Physiology is only partially endowed. It is clear, therefore, that if it is to continue to exist the Faculty of Medicine alone must absorb a large portion of the sum now being asked for.

Medical News.

UNIVERSITY OF LONDON.—A meeting of the Senate of the University was held on July 20th, the Vice-Chancellor, Sir Sydney Russell-Wells, in the chair. Dr. F. S. Langmead was appointed, as from August 31st, 1921, to the University Chair of Medicine tenable at St. Mary's Hospital Medical School. The Rogers Prize of £100 for 1921 was awarded to Mr. Lambert Rogers, M.R.C.S., L.R.C.P., for an essay entitled "The Surgical Treatment of Hyperthyroidism." The committee of the medical members of the Senate have elected Mr. H. J. Waring to be their chairman for the year 1921–22.

At examinations held recently the following candidates were successful in the subjects indicated:—

M.D. EXAMINATION.

Branch I., Medicine.—Simon C. de Silva Wijeyeratne, Univ. Coll. Hosp.; Geoffrey B. Dowling, Guy's Hosp.; William Feldman, Philip Hudson, and William A. E. Karunaratne, Univ. Coll. Hosp.; Gerald M. J. Slot (University Medal), St. Bart.'s Hosp.; John Heatly Spencer (obtained the number of marks qualifying for the University Medal), Charing Cross Hosp.; John G. Wardrop, Univ. Coll. Hosp.; Alfred Williams-Walker, Birmingham University; and Alfred Wills, Guy's Hosp.

Branch IV., Midwifery and Diseases of Women.—Kathleen M. Cogan, London Sch. of Med. for Women and St. Mary's Hosp.; Maud Gazdar, London Sch. of Med. for Women; Dennis H. Geffen, Univ. Coll. Hosp.; and Hilda G. Johnson and Muriel E. Landau, London Sch. of Med. for Women.

Branch V., State Medicine.—Lena C. Adam, London Sch. of Med. for Women and Univ. Coll. Hosp.; Hugh M. C. Macaulay, St. Bart.'s and Univ. Coll. Hosps.; Arthur B. Porteous, St. Mary's Hosp.; Rowan W. Revell, Middlesex and Univ. Coll. Hosps.; and Percy S. Selwyn-Clarke, St. Bart.'s Hosp.

Branch VI., Tropical Medicine.—James Fanstone, London Hosp. and London Sch. of Trop. Med.; and Clement H. Heppenstall, Leeds University.

M.S. EXAMINATION.

Branch I., Surgery.—Arthur L. Abel, Univ. Coll. Hosp.; Arthur W. Adams, Bristol University and London Hosp.; John A. W. Ebden, Westminster and London Hosps.; Claude H. S. Frankau (University Medal), St. George's Hosp.; Robert J. McNeill Love, London Hosp.; and Henry W. S. Wright, Univ. Coll. Hosp.

UNIVERSITY OF WALES: NEW PROFESSOR OF MEDICINE.—Dr. A. M. Kennedy, of the University of Glasgow, has been appointed Professor of Medicine in the Welsh National School of Medicine, Cardiff (University of Wales). Dr. Kennedy, who is at present senior assistant to the Muirhead Professor of Medicine in Glasgow University and one of the assistant physicians to the Glasgow Royal Infirmary, acts as Director of the Research Department at the Glasgow Royal Maternity and Women's Hospital on behalf of the Medical Research Council. He is the joint author of a monograph on cerebro-spinal fever and has contributed numerous papers to medical journals. He takes up his duties as Professor of Medicine and Director of the Medical Unit at Cardiff on Oct. 1st.

UNIVERSITY OF EDINBURGH.—At the graduation ceremonial in medicine, held in the M'Ewan Hall, Edinburgh, on July 15th, the following degrees were awarded:—

DOCTOR OF MEDICINE.

George A. Borthwick, Thomas L. Clark, *Thomas M. Davie (in absentiâ), Alfred V. Dill (first-class honours), †François P. Fouché, ‡Joseph G. Greenfield (first-class honours), *Robert L. Impey, James P. P. Inglis, Norman S. R. Lorraine, †Henry M. Moir, Bangalore Pasupulati Balakrishna Naidu, *Robert H. H. Newton, Pieter Johannes Olivier, Alexander C. Renwick (in absentiâ), William Gwernwy Richards, †William Stobie (in absentiâ), †John J. Thomson (first-class honours), and †Gerald G. Wray.

* Highly commended for thesis. † Commended for thesis.
‡ Awarded Gold Medal for thesis.

MASTER IN SURGERY.

David Holmes.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

James B. Aitken (second-class honours), George J. Alexander, Sydney E. Ammon, Thomas F. Andrew (in absentiâ), Flora T. F. Angier, Gilbert R. A. Armstrong, Charles W. Badger, Frederick E. L. Beck, Rosa M. Bickerton, John M. Black, Jacobus M. Bosman, William H. S. Boyd, Maeve Cluna Brereton, Andrew S. Burns, Donald Ian Cameron, John Campbell, Eric E. Candlish, Edward A. Carmichael, Edith K. Chandler, James H. Clarke, Jessie M'Cririe Craig (second-class honours), Nicholas S. Craig, Edward J. Craver, Grace Cumming, Edward Douglas Dingle (second-class honours), William Douglas, Alexander Dower, Stephanos J. Eapen, Geoffrey D. English, Harry D. Epstein, Isobel M. Finlayson (first-class honours), Edward M. Fraser, John S. Fulton, Katharine M'Laren Gifford, Elspeth L. Gilmour, Mary

that in future no member of a medical board whose decision was being appealed against should sit on the appeal tribunal. —Mr. MACPHERSON replied: The personnel of a medical appeal board should be entirely different from that of the board whose assessment is challenged. I am having inquiries made into the position in the area mentioned, and will communicate the result to my hon. friend.

Unemployment and Health Insurance Payments.

Mr. JESSON asked the Minister of Health if any consideration was given to insured persons under the Health Insurance Act, who, being out of employment through no fault of their own, were unable to continue their contributions, and were consequently greatly in arrears; and whether it was possible for them to be kept in benefit by deducting a small percentage from their sick pay, when it was allowable, until such arrears were paid up.—Sir A. MOND replied: Insured persons who have fallen into arrears through unemployment are given an opportunity of making a comparatively small payment in order to avoid any reduction or suspension of benefits. In view of the great amount of unemployment during the past 12 months, time during which such payment may be made has been extended to Nov. 30th next, and Approved Societies have been empowered to make a special concession in the case of members who have been unemployed for more than 26 weeks in the year. Any method such as that suggested by the hon. Member which involved the collection of the arrears only from members who fell ill would not be fair to the Approved Societies, as they would not be adequately recouped for the loss sustained by them in unpaid contributions.

THURSDAY, JULY 21ST.

Government's Housing Policy.

On the Report stage of a vote for the Salaries and Expenses of the Ministry of Health,

Mr. ASQUITH moved to reduce the vote by £100 in order to review the Government's policy in relation to the vital question of housing.

Mr. CLYNES urged that any other kind of building operations should have been prohibited until the pressing human needs of large masses of the population had been met.

Sir A. MOND, Minister of Health, denied that the Government was giving up the whole of the housing programme. The fact remained that the country had now a permanent burden for 60 years of £10,000,000 a year on the taxes in order to provide houses. We had incurred a commitment of over £600,000,000, an unprecedented contribution for the Exchequer to make, and the Government were trying to review the situation at a time when there were sufficient contracts and tenders approved to occupy for at least 12 or 18 months the whole building facilities of the country. He protested against being represented as indifferent or hard-hearted. Dealing with the question of slums, the right hon. gentleman said possibly it might have been better if they had begun at that end rather than undertaking so much new construction.

Dr. ADDISON defended his housing policy at the Ministry of Health, and urged that that policy was not his alone, but was that of the Government, of the House, and even of the country. He claimed that private enterprise would not meet the need, and the Government had no right to cut down expenditure on the removal of slums while they were spending £900,000 a month on Assyrian refugees.

Mr. LLOYD GEORGE said no country in the world had made such sacrifices as this country since the war. We had found more money for housing the working classes than the United States or any other country. Let Britain get credit for what she had done. They were only crying a halt; there would not be a single house the less built. The policy of the Government was not to stop housing, but to put it on a better and more business-like footing.

The amendment to reduce the vote was rejected by 251 votes to 67, and the vote was then agreed to.

Medical Research Awards.

Mr. BRIANT asked the Prime Minister whether, in view of the vital importance of medical research to the health of the nation, the prevention or cure of disease and the alleviation of pain, there could be provided a fund from which could be paid awards for discoveries or inventions which contributed to the general health of the community and which were placed gratuitously at the service of the public, pensions to those who had become totally or partially incapacitated in the course of research, and pensions to dependents of those who had died directly or indirectly as a result of their devotion to research.—Mr. BALFOUR (Lord President of the Council) replied: I see no ground for differentiating medical from other forms of scientific research, which may be of equal value to the community, and I doubt whether any system of pecuniary awards would in the long run be beneficial to science or medicine. The difficulty of apportioning merit for even the greatest of discoveries is often overwhelming; monetary awards would lead to jealousy instead of coöperation among research workers, and might prove to be an incentive to work for results that are sensational rather than for the advancement of scientific knowledge. The question was fully discussed at a deputation which I received on March 7th, 1920, at the Privy Council Office.—Mr. BRIANT: Does the right hon. gentleman recognise that in one branch alone, the research into the value of X rays, a great number of medical men have lost their lives, and their dependents get no recognition from the nation?—Mr. BALFOUR: I believe there were in the early days of X ray investigation very serious results to some medical men who lost their lives. Of course, their dependents are eligible for pensions. The Royal Bounty Fund is available for this purpose. Whether the Royal Bounty Fund is large enough is a question on which I am not competent to give an answer.

Unemployment and National Health.

Sir BURTON CHADWICK asked the Minister of Health whether, in view of the official report of his chief medical officer calling attention to the already apparent traces of the lowering of vitality in the health both of mothers and little children due mainly to unemployment and its effects, he was taking any special precautions to ensure assistance so far as it could be given in the coming winter to these victims of industrial unrest.—Sir A. MOND replied: I am having this matter carefully watched, and will give whatever assistance is possible within the limits of my financial resources.

FRIDAY, JULY 22ND.

New Licensing Bill.

Sir G. HEWART, Attorney General, moved the second reading of the Licensing (No. 2) Bill, which was agreed to.

Haslar Naval Hospital.

Commander BELLAIRS asked the Financial Secretary to the Admiralty the total possible number of beds in Haslar Royal Naval Hospital, and the maximum and minimum number occupied in the first six months of 1921.—Mr. AMERY replied: The total possible number of beds in Haslar Hospital is 1118. During the period Jan. 1st to June 30th, 1921, the maximum number occupied was 549 and the minimum 370.

Cosham Military Hospital.

Commander BELLAIRS asked the Secretary of State for War the total possible number of beds in Cosham Military Hospital and the maximum and minimum number occupied in the first six months of 1921; and whether he could state the distance of the hospital from the great naval hospital at Haslar.—Sir L. WORTHINGTON EVANS replied: There are 200 beds in Cosham Military Hospital; the maximum number occupied during the first six months of 1921 was 101, and the minimum number was 39 (on one day only). The approximate distance from the Naval Hospital at Haslar is 12½ miles by road and 7 miles by road and ferry.

MONDAY, JULY 25TH.

Whipps Cross Infirmary.

Mr. JOHN JONES asked the Minister of Health if he was aware that the West Ham board of guardians had offered to place shelters at Whipps Cross Infirmary for the accommodation of insured persons suffering from tuberculosis, and that these shelters were well adapted for the purpose of dealing with phthisis cases; and whether he could now give reasons why the offer of the board had been refused, in view of the great shortage of accommodation for this class of patient.—Sir A. MOND replied: A medical officer of the Ministry has now been instructed to visit this institution with a view to investigating the proposal of the guardians.

Illegitimacy Bill.

Mr. WIGNALL introduced a Bill "to extend and amend enactments relating to bastardy and to affiliation and certain other orders, and to provide for the legitimation of illegitimate persons by the marriage of their parents, and to amend the law relating to the rate of legacy duty and succession duty in the case of illegitimate persons, and otherwise to make further provision with respect to illegitimacy and illegitimate persons and their parents, &c." The Bill was read a first time.

TUESDAY, JULY 26TH.

Unemployment Benefit and Hospital Treatment.

Lieut.-Commander KENWORTHY asked the Minister of Labour whether a woman, the wife of a disabled ex-soldier, who was an insured woman and would otherwise be entitled to unemployed benefit, was not entitled to the benefit because her husband was receiving hospital treatment allowance, both living together.—Sir MONTAGUE BARLOW (Parliamentary Secretary to the Ministry of Labour) replied: A woman who is otherwise entitled to receive unemployment benefit is not disqualified by reason of the fact that her husband is a disabled ex-soldier receiving hospital treatment allowance.

cases, 16 (8 of each sex), and four emergency beds, which will be used for the temporary detention of those who come in under the influence of drink; this allotment of beds expresses in part the proportion which has existed in the past, in part the endeavour to provide a greater number of medical beds, and in part the consideration given to proper segregation of medical and surgical cases, convenience of nursing, and relation to the operating departments. The growth of the honorary staff since the infirmary was opened in 1868 by King Edward the Seventh (then Prince of Wales) is of some interest. At that time there were three honorary physicians and four honorary surgeons. The staff now numbers three physicians, three assistant physicians, four surgeons, four assistant surgeons, two ophthalmic and two aural surgeons, an obstetric surgeon and the honorary pathologist who is appointed by the special election committee, but who has to have the qualification that he is the professor of pathology in the University. In addition to these 20, there are the two officers in charge of the radiological department and the officer in charge of the venereal department, all of whom are appointed by the board on the recommendation of the faculty for a period of five years, and who are all eligible for re-election. In 1883 the resident staff numbered 7; there are now 14. The re-allocation of beds and cots above detailed is already being given effect to, but until the end of this year it will not have been fully carried out, and it will be some time before the open-air accommodation for children can be provided; when the process is completed the infirmary will have within its walls at least 552 beds and cots. In addition to these, the 86 beds at the two semi-convalescent hospitals at Cookridge really form an extension of the ward accommodation; to them are sent patients who require more nursing and attention than can be given at ordinary convalescent institutions. The maintenance of this great hospital makes heavy demands on the generosity of the public of Leeds and the surrounding district, and its finances are a source of anxiety to the board of management, but it is clear that the reputation of the infirmary has never stood higher than at present. Though Mr. Lupton has retired from the position of chairman he retains his seat on the board. He is succeeded by Mr. T. L. Taylor, who is not only a large employer of labour and a well-known business man, but a well-known cricketer, and will command the respect and confidence of all classes of the community.

St. George's Hospital Medical School.—The annual dinner will be held on Oct. 1st at Oddenino's Restaurant with Dr. H. A. Des Vœux in the chair. The usual notices will be sent during August.

British Hospitals Association Luncheon.—On July 30th, at the Royal Automobile Club, Lord Cave and the members of the Voluntary Hospitals Committee were entertained to luncheon by the British Hospitals Association. The Chairman (Sir Arthur Stanley) proposed the health of the guests, and expressed the gratitude of the Association to the Committee for the work done on behalf of the voluntary hospitals. Their double duty—the inquiry into the nature and extent of the difficulties with which the hospitals were faced and the suggestion of a way out of those difficulties—had been performed in a remarkably efficient way. Given a little time, the voluntary system could reassert itself and become as successful as it was in the past. Mr. Wade Deacon, supporting the toast, said that everyone connected with the voluntary hospitals appreciated the great trouble taken by the Committee in their work; as one who gave evidence before it he knew the shrewd interest and kindness displayed by its members. Viscount Hambledon spoke on behalf of the London hospitals; the latter, he said, had a problem of their own to solve; he hoped that before long increased receipts would remedy the urgent need now evident, and permit action along the lines recommended by Lord Cave's Committee. Lord Cave, responding, referred to the cordial support the Committee had received from all those interested in and connected with hospital work and from the Ministry of Health. With reference to the Government's grant of half a million pounds in answer to the Committee's urgent recommendation of a grant of a million this year and a possible million next year, if the hospitals had again to appeal for help in a year's time it would not be the fault of the Committee. If 1 per cent. of business profits in the country were applied to hospital purposes there would be no hospital problem. It was necessary that some fund for provincial hospitals, similar to King Edward's Hospital Fund for London, be established; and if hospitals were to prosper they must work more together than they had done in the past. The Marquess of Linlithgow then proposed the health of the Chairman; Sir Arthur Stanley, replying, made special mention of the valuable services rendered to Lord Cave's Committee by its secretary, Mr. L. G. Brock, who was now secretary of Lord Onslow's Commission.

Parliamentary Intelligence.

HOUSE OF LORDS.

Wednesday, July 20th.

Hospital Finance.

Viscount Burnham asked His Majesty's Government whether they had fully considered the Report of Lord Cave's Committee on hospital finance, and, if so, what further steps they would take to put the system of voluntary hospitals on a more satisfactory footing, particularly in relation to the Poor-law infirmaries. He said he asked the question not in antagonism to the Committee presided over by Lord Cave, to whom the whole hospital world was much indebted for the care that he had taken in the preparation of the Report. But that Report was of necessity provisional, and the remedies suggested were in the nature of a stop-gap. The London Hospital had closed down 200 beds and King's College Hospital 100 beds. On the other hand, this was only one phase of what had been called the national health problem, and the hospitals were only part of the national health policy. That things were not as they might be they could see well enough when in the Report of the Chief Medical Officer of the Ministry of Health it was stated that in England and Wales there was lost to the nation every year among the insured population only, and excluding losses due to sickness for which sickness and disablement payment was not payable, the equivalent of the work of 270,000 persons. There was a clear case for the renewal of the mandate of this Committee and for the extension of its reference. What had been done now would not do much more than cover the year's deficit; and yet the causes lay so deep that unless the problem was considered as a whole, and now, the waste of public money would be great, and the results were not likely to be satisfactory. All who were connected with the administration of voluntary hospitals were pleased that the Committee emphatically affirmed and approved the voluntary principle. Experts speaking at various conferences believed that it created a free and expansive atmosphere for medical research and medical treatment, and that if State or even municipal control were substituted it would crab and stereotype the methods of administration and be fatal to scientific advance as well as to expert treatment.

Hospitals and National Health Insurance.

There was, Lord Burnham went on to say, a clear case for asking the Committee to report on two great subjects long overdue. He meant the relation that the system of national health insurance bore to the rest of the problem of national health, and particularly to the provision of hospitals, both general and special; and secondly, the relation of the Poor-law infirmaries to the voluntary hospitals. In regard to insurance, he thought that the Committee had much understated the case. It was recognised in the Act of 1911 that hospital treatment was necessary as part of the general relief given to insured persons, many of whom were well within the category of the sick poor. The Committee did not appreciate the degree to which the obligations and the burdens of hospitals had been increased by the National Insurance Act. Hospital treatment was absolutely necessary to the obtaining of satisfactory results under that Act. It was not the case that the general practitioners had given all that the Act demanded, or all that they might have given, if it had not been for the goodwill and the zealous assistance of the hospital authorities. Before the Act was passed a vast amount of sickness and distress was hidden in the back streets of the great cities and never brought to light. Much of it in the country villages never obtained proper attendance, still less remedial treatment. When the panel practitioners began to appreciate the extent of their duties they found ready to their hand, and especially in the metropolitan area, a great system of voluntary hospitals to which they could turn if they were in the least difficulty; and there grew up the practice of sending their patients to hospital with letters of recommendation, which, as a rule, insured the cases being dealt with, even when they were not of great urgency. The whole system of prophylactic treatment was only slowly appreciated. The Exchequer was getting indirectly the benefit of a vast amount of hospital expenditure which would have been unnecessary if the National Insurance Act had not been passed. The calls upon the hospitals were increasing. The expert consultants were now going into a sphere of treatment which was formerly left to the general practitioner, and as disease was diagnosed with greater fullness and accuracy so the demand for skilled treatment was always increasing. A clear case existed under the Act for obtaining a contribution ut of the surpluses of the Approved Societies such as might

Notes, Short Comments, and Answers to Correspondents.

INDUSTRIAL HYGIENE: ITS RISE, PROGRESS, AND OPPORTUNITIES.[1]

BY SIR THOMAS OLIVER, M.D. GLASG., F.R.C.P.

IT is just over a century ago since the British Parliament turned its attention to the fate of children employed in the mines and factories of this country, and little more than half a century ago since diseases due to occupation received similar recognition. Great Britain was the pioneer of industrial legislation. The utilisation of water power and steam led to the rise of the factory system and to the growth of large towns. The "Industrial Revolution," which began about 1740, and the inventions which preceded and followed it, not only placed us as a nation in a high position in the world of commerce and made us wealthy, but it created new methods of employment associated with the subdivision of labour, as well as a new class of workers to meet the requirements. It also initiated problems towards the solution of which, as the statesmen of the time had no experience to guide them, the laws which they framed could at the best be but only tentative and a makeshift. While the introduction of machinery made labour in the factories in one sense less irksome, it led to the employment of women and children, many of whom, owing to the long hours and low wages, rapidly broke down in health. with no financial assistance from the State or from the industry to fall back upon, so that to ill-health were added the distressing circumstances of poverty and starvation with only the workhouse to look forward to. In order to prevent physical degeneration of the working classes it became necessary to improve the conditions under which labour was carried on in mine and factory by shortening the hours of labour for women and children, and by raising the age of child workers. The employment of children of seven years of age in our coal-mines and factories, and the harsh treatment extended by overseers to them, since they were frequently beaten or handled roughly when they were found asleep at work, form unpleasant reading in the pages of the industrial legislation of this country.

Industrial Legislation.

From the first decade of last century onwards to the Victorian period Parliament time and again shortened the hours of labour, restricted the employment of children, and improved conditions within the factories. but even as late as 60 years ago little had been done to instil into the mind of the people the association of certain diseases with particular occupations, and how these diseases might be prevented. Thackrah, in 1831, had written upon the subject, and J. T. Arlidge, in 1892, had published his monumental work, but occupational diseases as a class had not yet caught on with the medical profession, and so matters drifted. Sir John Simon, at the dawn of the public health movement in this country, recognised how closely identical was the health of workers with the object sought to be secured by a public health service, and that in the prevention of disease lay one of the most important duties of the medical profession. To-day the preventive side of industrial medicine is regarded as even more important than the curative. Industrial hygiene may be said to have merged out of, or to have been a continuation of, Parliamentary interference with the claims of employers to utilise labour almost to its breaking point. Occupation was never meant to cripple workmen, cause ill-health, or induce early death. It was thus that medicine was drawn into the social movement in which it plays an honoured part to-day. In few fields of human activity has the call for preventive medicine been greater than the various industries of this country, with their former high mortality and sickness rates. Society, in the past, kept itself too far aloof from knowledge of the conditions under which certain trades were carried on, and even the workers themselves were not always aware of the dangers to which their employment exposed them. Ignorance is responsible for many of the calamities which overtake us. It became necessary to instruct workers and employers in regard to occupation and health, for to have knowledge is to be forearmed. Regulations drawn up by the Home Office, and meant for the welfare of workers, have from time to time been challenged by both employers and employed, and there is no objection to this, since at a conference of the parties concerned conflicting opinions may be modified, or, failing this, a compromise is effected, and work allowed to continue, during which fresh regulations can be given a trial.

The Widened Scope of Industrial Hygiene.

Within the last few years the scope of industrial hygiene has widened. It includes not only consideration of the conditions under which work is carried on, the hours of labour and diseases incidental to occupation, but it deals with the physical effects of work as seen in fatigue and how hours of work and rest may be correlated so that there may be obtained the maximum of production with the minimum of effort, also that the hours of respite from labour may be made sufficiently long for recovery from exhaustion to take place. The tendency has been to remove from labour any serfage element which may have clung to it as a remnant of bygone days, and to recognise that men and women are not mere machines, but that they are entitled to the opportunities of improving themselves mentally and physically. To-day industrial hygiene is no longer the affair of one nation but of all the advanced nations. The creation of the International Labour Bureau under the ægis of the League of Nations has raised industrial medicine to a higher platform, so that while the health of the workers is one of the main objects, and production is regulated by the physical fitness of the worker and by the hygienic conditions under which labour is carried on, the fact that industrial medicine has become international will incite backward nations to aim at securing a higher standard of health for their workpeople, as well as more efficient means of increasing production. Arising out of legislation passed for improving conditions of labour and shortening of the hours of work, and proceeding through medical supervision of workers and the elimination of the unfit as well as the substitution of comparatively harmless for harmful methods of production, of industrial medicine it may be said that although it has made such rapid strides that many of the results obtained have become fresh energising influences in the life of nations, yet many opportunities for good still lie in front of it.

Medical examination of workers before commencing their industrial career would no doubt create hardships, but the ultimate gain would transcend all these. Even with the ordinary precautions taken there would still be found a certain number of persons who would break down in health earlier than others, either as the result of diminished vital resistance or of idiosyncrasy.

Sir Thomas Oliver then gave an account of the transformation from dangerous into comparatively safe industries those of lead-mining and match-making, and discussed briefly the pathology and prevention of carbon-monoxide poisoning, adding a short survey of the preventable hazards to which coal-miners were formerly subjected. He continued:—

Fatigue.

There is one side issue of industrial hygiene which has recently attracted attention—the subject of fatigue. A hundred years ago the world moved, as the saying is, more slowly than it does to-day. Men took things more quietly; there was neither the strain nor the competition characteristic of modern times. Hard work was followed by fatigue then as now, but it affected principally the muscular system; to-day it falls more upon the nervous system. Collective work is carried on in over-heated factories amid the din of machinery and it demands close attention. The reality of fatigue was brought home to us by the large number of men and women who broke down in munition work during and after the war. There is a limit beyond which the human machine cannot produce satisfactorily. Fatigue as subjectively experienced is a series of ill-defined sensations not always localisable, attended by disinclination for work and by a desire to rest. Professor Drever[2] thinks that the word "weariness" pretty accurately describes the subjective state in the individual, and that objectively fatigue can best be defined in terms of output, as shown by a lowered efficiency in the organism, and revealed by impairment of the quality, and diminution of the quantity, of work done. The delicate nerve cells and nerve endings of the human body become readily fatigued, but if we take fatigue to mean an inability to carry on as previously, then fatigue is not confined to living tissue alone, for a similar event occurs in the inorganic world. Steel wires when over-strained play out and behave as tired nerves. It would be of the greatest assistance if we could with a certain degree of definiteness ascertain just to what number of hours a man can work before his energy begins to fail, for once this takes place, if work is continued, it is unprofitable. Clearly the number of hours of work cannot be the same for all individuals or for all trades. As regards fatigue, much will depend upon the previous health and upbringing of the worker, how he is fed and housed, and how he spends his leisure hours.

The recent war has been followed by disastrous consequences in the case of many of the discharged soldiers.

[1] Abridged from a Special Address delivered at the Eighty-Ninth Annual Meeting of the British Medical Association.

[2] Drever: The Psychology of Industry, p. 61. Methuen.

was going to increase, and any estimates which the noble earl might make as to the necessity of institutional treatment would be very much under the mark. The whole tendency of modern life was to increase the need of institutional treatment. The diagnosis of disease was no longer the work of a single individual; it was done by the coöperation of several individuals; and coöperation required equipment and organisation, and these required provision. That was the scientific reason; the next was the economic reason. Every time they increased complexity in the investigation of illness they increased the cost. Every new invention cost an institution an increase in expenditure. This meant that the number of people who could defray the whole cost of their illness went steadily down. The only solution was an increased provision of institutional treatment. The third was the social reason. Homes were now much more difficult to manage than they were, and the more narrow and restricted the income the greater the difficulty. In some parts of the country, if the lady of the house ventured to wish to have a baby, the servants very often desired to leave. They must take a wider view of hospital needs than that represented by the case of the sick poor.

The Place of Poor-law Hospitals.

One way by which the Poor-law infirmaries could be used in certain districts was by supplementing the work of the general hospitals by arrangement; but they should not start business on their own, as had been done at Bradford. The medical talent of a district nearly always centred round the voluntary hospital, which enabled that hospital to give a lead in treatment and medical policy. Another way in which Poor-law infirmaries could by voluntary means assist the community was by setting aside wings or blocks of beds for paying patients or supported by paying patients. But it was necessary that the boards of guardians, or the body that had charge of these infirmaries, should make no provision for the medical care of these people. All they should do was to provide the hotel part of the business, and the nursing equipment and machinery. The patient's own doctor should follow the patient into that institution, and in that way they would support the central principle of all medical progress in this country, and that was the provision of the fabric side by side with freedom of relations between doctor and patient. If once they allowed the guardians to provide medical aid for these patients they were on the slippery slope of municipalisation of medicine. Although the country was in dire need and straitened financial circumstances it would be helpful if the Ministry of Health could lay down the outlines of a health policy. What was the policy that was going to guide these services, and especially the curative services, during these lean years when it was admitted that expenditure must be cut down to the minimum? He suggested that there were two lines of policy—first, to maintain all essential services now, not more than that; and then this further line of policy: they could utilise these lean years to lay down the foundations of a constructive policy which could be commenced when the finances of the country permitted an advance in that direction.

Viscount CAVE said that the House had been more than interested in Lord Dawson's speech. He was sure that the insurance societies owed a great deal both pecuniarily and otherwise to the hospitals, and he hoped they would recognise that help by making larger contributions to their funds. If it were necessary, as he thought it might be, to modify the law, in order to enable full coöperation to take place between the Poor-law infirmaries and the voluntary hospitals, he hoped the Government would introduce a Bill for that purpose without waiting for the introduction of the general measure which had been foreshadowed.

HOUSE OF COMMONS.

TUESDAY, JULY 19TH.

Death Certificates.

Mr. WATERSON asked the Minister of Health how many deaths were certified by registered practitioners in each year during the past ten years; how many deaths were uncertified, and how many of the latter deaths were reported to coroners. —Sir A. MOND replied: It is not possible to state the number of deaths which were certified by a registered medical practitioner or the number of those which were not so certified. The available statistics are derived from death registration; and a death which is the subject of an inquest is registered on the certificate of the coroner, whether it had or had not been previously certified by a registered medical practitioner. The figures of deaths registered respectively on the certificate of a registered medical practitioner, on the certificate of a coroner, and without either a medical certificate or an inquest are as shown in the table. With regard to the last part of the question, registrars of births and deaths have been required since March 2nd, 1914, to report all cases of uncertified deaths to a coroner, but complete information as to the number reported in the previous years is not available.

—	Registered on certificate of registered practitioner.	Registered on coroner's certificate after inquest.	Uncertified deaths on which no inquest was held.
1911 ..	483,944	37,200	6,666
1912 ..	443,938	36,668	6,333
1913 ..	462,396	36,419	6,160
1914 ..	472,768	37,695	6,279
1915 ..	515,441	39,128	7,684
1916 ..	463,929	36,760	7,528
1917 ..	456,666	34,704	7,552
1918 ..	570,605	33,012	8,244
1919 ..	466,017	31,488	6,698
1920 ..	429,426	30,995	5,709

WEDNESDAY, JULY 20TH.

Optical Glass and Medical Research.

The House went into Committee on the Safeguarding of Industries Bill, Mr. J. HOPE in the chair. The Committee stage of the Bill was completed.

Public Representation and Hospital Grants.

Mr. BRIANT asked the Minister of Health if grants out of public funds were made to hospitals if provision would be made for representatives of the public on the governing bodies.—Sir A. MOND replied: I will bring my hon. friend's suggestion to the notice of the Hospitals Commission, but I am disposed to doubt whether a non-recurrent grant would justify requiring hospitals to make a permanent change of this kind in the constitution of their governing bodies.

Effect of Summer Time on Children.

Sir ROBERT THOMAS asked the President of the Board of Education whether he had requested the educational authorities to ascertain the views of head teachers, school medical officers, and others on the effect of summer time on the children; if so, whether he had yet received this information; and whether such information would be published before the Summer Time Bill now before Parliament became law.—Mr. FISHER replied: I will send the hon. baronet a copy of a Circular (No. 1215) which was addressed by the Board to local education authorities in England and Wales in May last. The answers to the Circular have not yet been received.—Colonel FREMANTLE: Will any such information be balanced by the opinion of medical officers of health on adults: will the one view be balanced against the other?—Colonel ASHLEY: May we have the information before the Summer Time Bill comes up again for discussion?—Mr. FISHER: If possible.

Dangers of Lead Paints.

Captain BOWYER asked the Secretary for the Colonies whether he was aware that the International Labour Conference, sitting at Geneva in October next, would have before it a proposal for the prohibition of the use of white lead in painting; that this proposal was viewed with alarm by the Government of the Commonwealth of Australia because such a prohibition would cause the closing down of the Broken Hill lead mines of New South Wales, which were of primary importance to Australia; that such a prohibition would have a similar effect upon the lead mines of Burma and Rhodesia; and whether he would cause instructions to be given to the representatives of His Majesty's Government at the International Labour Conference to ensure that careful consideration might be given to the possibility of dealing effectively by precautionary regulations with such dangers of poisoning as were incidental to the use of paint rather than by a method which would have such serious consequences for imperial interests.—Mr. CHURCHILL replied: The answer to the first part of the question is in the affirmative. As to the second part, I have received no representations as regards Rhodesia. The Commonwealth of Australia and India are both original members of the International Labour organisation under Article 387 of the Treaty of Versailles, and provision is made for their direct representation at International Labour Conferences under Article 389. As to the third part, I understand that the instruction to be given to the representatives of His Majesty's Government will be settled later.

Medical Board Appeals in Durham.

Mr. HEYWARD asked the Minister of Pensions whether in the Easington district, county Durham, appeals against decisions of the medical board were heard before another tribunal having the same chairman as the medical board whose decisions were being appealed against; if this was so, whether he was aware that thereby a sense of grievance and injustice was caused in the minds of appellants; and whether he will give the necessary instructions to ensure

JOHN KENSINGTON, J. H. HERTZ (Chief Rabbi),
ALBERTA SANDWICH, ROBERT F. HORTON,
LOUISE CREIGHTON, FRANK LLOYD,
MARY ST. HELIER, J. F. GREEN (Chairman).

July 19th, 1921.

TRIFOLIUM STELLATUM AT SHOREHAM.

To the Editor of THE LANCET.

SIR,—In the obituary notice of the late Sir George Savage, appearing in your issue of July 16th, a personal friend mentions an unsuccessful search for the star clover at Shoreham, and adds that it is still there. I should be glad to hear if this is really so. Over 30 years ago I can remember Mr. G. C. Druce showing me a pocket-case full of the stellate fruits he had gathered on the beach. During the decade 1902–11 I searched every year for the plant, but only found it (and then very sparingly) on two or three occasions. The erection of bungalows, formation of roads, and other human activities resulted in its practical extinction, so far as my limited observation went. As Shoreham beach is the only British habitat for a rather striking plant, I should be very glad indeed to hear that it was still holding its own. Perhaps some of your South Coast readers have some recent information on the point? I may add that from seeds obtained at Shoreham I have grown specimens of the plant in my garden for many years past.

I am, Sir, yours faithfully, J. E. SAUL.

Analytical and Bacteriological Department, Savory and
Moore, Ltd., 143, New Bond-street, London. W.,
July 19th, 1921.

PUBLIC HEALTH AT COLOMBO, 1919.

IN his report on the conditions of public health at Colombo during 1919, Dr. W. Marshall Philip, the medical officer of health, commences by stating that the birth-rate, 21·7 per 1000, was the lowest recorded for 15 years, whilst the death-rate, after falling from 39·8 in 1906 to 24·3 in 1917, had risen to 28·0 in 1918 and 28·8 in 1919; the infant mortality, having fallen from 419 per 1000 births in 1903 to 231 in 1916, had risen to 251, 266, and 271 per 1000 in the three years 1917–1919 respectively. The population is estimated to have been 271,616 in the middle of 1919, but the correctness of this is open to doubt, especially in certain wards, where a large number of new buildings have been erected. Among the various races included in this total, the native Sinhalese naturally form the majority (121,848), after whom come Tamils from Southern India (65,797), Moors (47,854), Burghers (Dutch or Portuguese, 17,812), and Europeans (3795), the remainder consisting of Malays and others. The birth-rate varied from 12·1 amongst Tamils to 32·0 amongst Malays; for Europeans it was 17·1, for Moors 17·6, and for Sinhalese 27·9. The general crude death-rate of 28·8 is to be compared with the decennial average (1909–18) of 28·2; if corrected for deaths in hospital of non-residents, and for age and sex constitution, the ratio becomes 29·7, "which is the nearest approach to the true death-rate of Colombo which can at present be obtained." The corresponding ratio for 1918 was 29·4 per 1000. As regards the different races making up the total (crude) ratio of 28·8, for Sinhalese the ratio was 34·3, for Moors 21·2, for Tamils 23·1, and for Europeans 17·1 per 1000; if corrected for deaths in institutions, this last figure becomes 9·8, practically the same as in 1918, when it was 9·5 per 1000. The infantile mortality ratio (271 per 1000 births) was higher than in any year since 1913, when it had been 286. Dr. Philip discusses this matter and "is forced to the conclusion that one of the principal causes, if not the chief cause, is lack of proper nourishment for the pregnant women and their infants," probably owing to increased cost of living since the war broke out. Owing to failure of the monsoon in 1918, the Indian Government restricted the export of rice. The normal monthly import into Ceylon of 30,000 tons fell to less than half in May, and less than a quarter in June; food control was initiated on May 9th, and rationing of rice on June 10th. The cost of living has been increased in Ceylon, as elsewhere, but Dr. Philip clearly shows that there was no "starvation," though there was a good deal of "privation" and anxiety. The daily crowding together of the people entailed by the introduction of the rice depôt system was apparently responsible for an increase in enteric fever and measles; and the storage of grain in buildings not rat-proof resulted in a number of cases of plague in the last three months of the year. The proportion of septicæmic cases (57·1 per cent.), and the very high case-mortality (91·3 per cent.) showed that there had been no material reduction in virulence. No cases of cholera occurred in Colombo, but ten were admitted to hospital from the port, and one from outside the town. There were only three cases of small-pox, two having acquired infection in India. Primary vaccination was performed in 6637 children, the number of births in Colombo during the year having been 5907. This is very satisfactory, and should be an example to that unfortunately large number of persons in the United Kingdom, who are either unable or unwilling to realise their responsibilities in regard to this matter. Dr. Philip's is a most comprehensive report, fully illustrated with plans and diagrams, and contains much other matter of interest.

ACTION OF THE HEART AFTER DEATH.

SOME interest has been evinced in our correspondence columns by Sir Dyce Duckworth (July 2nd), Sir William Milligan (July 9th), and Surgeon Commander D. H. C. Given (July 23rd) in the circumstances of the death of a man at Willesden whose heart continued beating long after respiration had ceased. At the inquest on June 20th a verdict of "Death from natural causes" was given, the circumstances of the case being as follows. The man became drowsy about Whitsuntide with severe pains in the head, but continued to work until a fortnight before his death, when he became worse. On admission to the hospital he was suffering from drowsiness, stiffness of the muscles of the back, and headache. It was considered advisable to obtain a sample of his cerebro-spinal fluid, and to this end he was anæthetised with a mixture of ether and chloroform at 11.20 A.M. on June 16th. Some fluid was drawn off—the whole operation took only half a minute, but the man ceased to breathe, though his heart continued to beat well. Artificial respiration was continued up to 7.30 P.M., when the heart ceased beating. The post mortem revealed a tumour on the right side of the brain, which proved to be a sarcoma. A tracing of the heart was taken at 5.30 P.M.

As is well known, in chloroform anæsthesia the respiratory movements may suddenly cease, and after a time be resumed. The heart beats, however, unlike the respiratory movements, do not essentially depend on the integrity of a nerve centre in the medulla oblongata. In fact the heart contains in its own walls and perhaps in its own muscular fibres the secret of its own rhythm. The fact that an excised heart in some animals will beat for days proves this. Those who are not acquainted with the marvellous powers of endurance of the heart muscle regard the heart itself as a singularly vulnerable organ. The very opposite is the case, and it will go on beating for quite a long time, even under seemingly very unfavourable conditions. Its demands are small but specific. In the present case artificial respiration, it appears, was kept up for about seven hours, the heart only ceasing to beat at the close. With the artificial movements of the chest wall the blood would be aerated to a certain extent, and as the heart still retained its automatic rhythmical movements, this partly aerated blood was sufficient to maintain the heart beat, but would not appear to have had the properties necessary for the excitation of the respiratory centre on the one hand, and the maintenance of consciousness on the other. We know how sensitive cerebral tissue is to the lack of oxygen and other conditions.

Prof. C. Richet some years ago obtained a film of the beating of a dog's heart with the chest opened, artificial respiration being kept up or arrested at the will of the operator. With cessation of the artificial respiratory movements, after a time the heart—engorged with blood—ceased to beat. On resumption of the artificial respiration, after a time the congested condition of the heart was relieved, and it slowly but surely resumed its beat. This could be done time after time. In the case recorded above the steady artificial maintenance of the respiratory movements, no doubt, kept the blood sufficiently aerated to ensure the long-continued beating of the heart. At what hour did "death" in the eye of the law take place? With the cessation of normal unaided respiration and loss of consciousness, while the heart still continued to beat; or only when normal respiratory movements and consciousness had long ceased; or when the heart itself ceased to beat?

The law presumably would regard the question as one of fact, depending upon the evidence of the medical witnesses. It would probably ask that the time should be fixed when all symptoms of life ceased, and suggest that this should be treated as the time of "death." It would be difficult to maintain otherwise. In the above case artificial respiration was kept up in the not unreasonable hope that natural respiration and consciousness might eventually be restored, and a medical witness could hardly say that a person was beyond doubt "dead" at a time when he himself, guided by the experience of his profession in other cases and by the observed action of the heart, was treating him as though he were, or might be alive. The question of the exact moment at which life ceases is not often of importance, but it may affect the devolution of property. In the case of the subject of the inquest referred to, if someone had died at 1 P.M. on June 16th leaving to him a sum of money or land in fee simple, the hour of his death might become of extreme interest to his children and to others affected by the same will.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

TUESDAY, *August 2nd.—Opening of Vacation Course.* 10 A.M., Surgical Registrar: Demonstration of Cases (Surgical Wards). 2 P.M., Dr. Burnford: Medical Out-patients. 2.30 P.M., Mr. Addison: Demonstration of Cases (Surgical Wards). 4.30 P.M., Lecture:—Dr. Pritchard: Intravenous Therapy.

WEDNESDAY.—10 A.M., Dr. A. Saunders: Medical Diseases of Children. 11 A.M., Mr. MacDonald: Demonstration of Cystoscopy. 12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen. 2 P.M., Mr. Gibb: Eye Department. 4.30 P.M., Lecture:—Mr. Addison: Carcinoma of the Breast.

THURSDAY.—11.30 A.M., Obstetrical Registrar: Gynæcological Demonstration. 2 P.M., Dr. S. Pinchin: Medical Out-patients. Mr. MacDonald: Surgical Out-patients. 4.30 P.M., Lecture:—Dr. A. Saunders: Rickets.

FRIDAY.—10 A.M., Mr. D. Buxton: Dental Department. 12.15 P.M., Dr. Burnford: Applied Pathology. 2.30 P.M., Dr. Pritchard: Visit to Medical Wards. 4.30 P.M., Clinical Lecture:—Mr. Banks Davis: Throat, Nose, and Ear.

SATURDAY.—10 A.M., Medical Registrar: Demonstration of Cases (Medical Wards). 2 P.M., Mr. Sinclair: Surgical Out-patients.

Daily:—10 A.M., Visit of Post-Graduates to Wards. 2 P.M., In-patient, Out-patient Clinics and Operations.

Appointments.

BELLWOOD, K., F.R.C.S. Eng., has been appointed Surgeon to the Albert Dock Hospital of the Seamen's Hospital Society.

HAUXWELL, FRANK, M.B., Ch.B. Glasg., D.P.H. Camb., Medical Officer of Health and School Medical Officer, County Borough of St. Helens.

MCILROY, J. HAMILTON, D.Sc., M.B., Ch.B. Glasg., Lecturer on Diseases of the Eye in the Lady Hardinge College, Delhi.

PINNOCK, D. DENHAM, M.B., B.S. Melb., F.R.C.S. Eng., Assistant Surgeon to the London Temperance Hospital.

SLOT, GERALD M., M.D. Lond., Medical Registrar to Charing Cross Hospital.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Jun. M.O. £500.
Bedford County Hospital.—H.S. £200. Asst. H.S. £150.
Bethlem Hospital.—Res. H.P. £25 per quarter.
Birkenhead Borough Hospital.—Jun. H.S. £200.
Birmingham General Hospital.—Res. M.O. £155.
Birmingham, Queen's Hospital.—Surg. Registrar. £100.
Bradford Royal Eye and Ear Hospital.—Hon. Asst. Ophth. Surg.
Bradford Royal Infirmary.—H.S. £200.
Carlisle Non-Provident Dispensary.—Res. M.O. £300.
Devonport, Royal Albert Hospital.—H.S. £200.
Downpatrick, Down District Asylum.—Sen. and Jun. Asst. M.O.'s. £350 and £300 respectively.
East Suffolk County Education Committee.—Female Asst. Sch. M.O. £500.
Evelina Hospital for Children, Southwark, S.E.—H.P., H.S. Each £160.
Freemasons Hospital and Nursing Home, 237, Fulham-road, S.W.—Res. M.O. £250.
Glasgow, Woodilee Mental Hospital, Lenzie.—Asst. M.O. £350.
Gloucester County Asylum.—Jun. Asst. M.O. £350.
Great Northern Central Hospital, Holloway, N.—Dental Surg.
Halifax Royal Infirmary.—Second H.S. £250. Third H.S. £200.
Hull Royal Infirmary.—V.D. and Cas. O. £250. Asst. H.S. £150.
Jersey Poor House Infirmary.—M.O. £750.
Kent County Council, Lenham Sanatorium.—Asst. M.O. £400.
Leeds Public Dispensary.—Sen. Res. M.O. £250.
Leicester Royal Infirmary.—H.P. £200.
London University.—University Readership in Pathological Chemistry. £700.
Loughborough and District General Hospital and Dispensary.—Res. H.S. £200.
Manchester, Ancoats Hospital.—H.S. £150.
Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Res. M.O. £350.
Middleton-in-Wharfedale Sanatorium.—Asst. M.O. £500.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Res. Cas. O. £200.
Newport (Mon.) Royal Gwent Hospital.—H.S. £200.
Nottingham City Asylum.—Med. Supt. £700.
Oxford, Radcliffe Infirmary and County Hospital.—Cas. H.S. £200.
Plymouth, South Devon and East Cornwall Hospital.—H.P. £150.
Preston County Asylum, Whittingham.—Asst. M.O. £572 18s.
Queen Mary's Hospital for the East End, Stratford, E.—Cas. O. £150.
Royal Dental Hospital of London, Leicester-square, W.C.—Whole-time Officer. £800.
Royal Naval Medical Service.—Surg.-Lieuts. 26s. 6d. per diem.
Seamen's Hospital Society, Greenwich, S.E.—H.P. H.S. Each £150.
Singapore Municipality.—Bacteriologist. 9000 dollars.
Stockport General Infirmary.—Sen. Res. M.O. £300.
Swansea County Borough.—Asst. M.O. £500.
Torquay, Torbay Hospital.—H.S. £200.
Union of South Africa (Natal Provincial Administration).—House Surgeons, Grey's Hospital, Pietermaritsburg. £400.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Cas. Sorting Officer and Anæsthetist. £100.
West End Hospital for Nervous Diseases, 73, Welbeck-street, W.—Clin. Asst.
Westminster Hospital, Broad Sanctuary, S.W.—H.P.
Wigan County Borough.—Tuberculosis Officer and Asst. M.O.H. £550.
Winsley Sanatorium, near Bath.—Asst. Res. M.O. £250.
Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £350.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of the following vacant appointment: Tisbury (Wilts).

Births, Marriages, and Deaths.

BIRTHS.

FINNY.—On July 22nd, at "Tamesa," Kingston-hill, Surrey, the wife of William Evelyn St. Lawrence Finny, M.D., J.P., Barrister-at-Law, Mayor of Kingston-upon-Thames, of a daughter.

GOOD.—On July 13th, at Moorland-road, Leeds, the wife of John Good, M.R.C.S., L.R.C.P., of a daughter.

HOFFMAN.—On July 15th, the wife of H. Drummond Hoffman, M.B., B.Sc. Camb., Tatsfield, Surrey, of a son.

HORSBURGH.—On July 12th, at Eastmount, Dover-street, Ryde, the wife of E. Leslie Horsburgh, M.D., of a son.

OVEREND.—On July 17th, at Lynton Lodge, Cadishead, Lancs., to the wife of H. F. Overend, M.R.C.S., L.R.C.P.—a daughter.

PURSER.—On July 22nd, at Inkerman Barracks, Woking, the wife of Lieut.-Colonel L. M Purser, D.S.O., R.A.M.C., of a son.

SELBY.—On July 20th, at S. Ealing-road, W., the wife of E. J. Selby, M.R.C.S., L.R.C.P., of a son.

SLADDEN.—On July 24th, at Cheltenham House, Eaton Grove, Swansea, to Dr. and Mrs. Arthur Sladden—a son (Robert Arthur).

STEPHENS.—On July 19th, at Crouch-hill, the wife of Capt. H. F. Stephens, R.A.M.C., of a son.

WAKEFORD.—On July 23rd, at Fulham-road, S.W., the wife of V. D. C. Wakeford, M.B., B.S., of a son.

MARRIAGES.

CLARKE—BLAKE.—On July 23rd, at St. Marylebone Parish Church, James Kilian Clarke, M.B., Ch.B., D.P.H., Lecturer in Pathology and Bacteriology at the School of Medicine, Cairo, to Evelyn Muriel, daughter of Mr. and Mrs. A. H. Blake, of Brondesbury, N.W.

DEATHS.

DOWNIE.—On July 21st, at Cragmohr, Shandon, James Walker Downie, M.B., C.M., F.R.F.P.S. Glasg.

REYNOLDS RAY.—On July 8th, at 4, Coventry House Chambers, Haymarket, after a long illness, Edward Reynolds Ray, M.R.C.S. Eng., L.S.A., formerly of Dulwich Village, S.E., aged 79.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

stimuli is sufficient to substantiate the acceptance of the popular psychology of "mixed feelings." We have seen that movements common to other states of activity may occur as concomitants of different affective states.

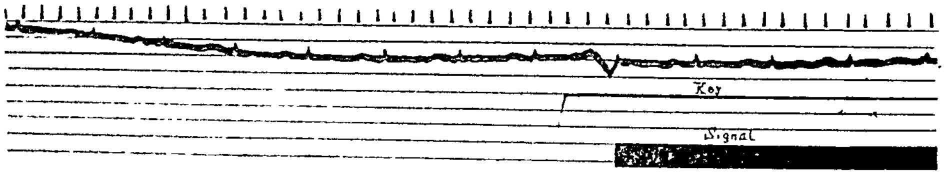
PROBLEM OF ORIGIN OF AFFECTIVE STATES.

However much we may wish to confine our study of the neuroses to a purely objective basis we are unable to evade the question as to whether an affective state is to be regarded as conditioned by the physiological changes of bodily activity, or whether such changes occur as the organic resonance to a preceding affective state. Our whole system of the interpretation of the emotional aspects of the neuroses must be influenced by our answer to this problem. Ancient writers answered it in no uncertain fashion:

> "Cor ardet, pulmo loquitur, fel commovet iras,
> Splen ridere facit, cogit amare jecur."

Aristotle and his school of course recognised no other bodily mechanism for mental processes than that of the thoracic viscera. The Stoics, for the most part, rejected the brain as the seat of mind, and Zeno, Chrysippes, Diogenes, and Apollidorus were unanimous in proclaiming the heart to be the seat of the emotions. It would be too lengthy a task to follow the causal attribution of the affections to visceral changes throughout the Middle Ages. In recent times it has been revived in the James-Lange theory of emotion. I cannot do better than give the theory as propounded in James's original words: "Common sense says we lose our fortune, are sorry and weep; we meet a bear, are frightened and run; we are insulted by rivals, are angry and strike. The hypothesis here to be defended says that this order of sequence is incorrect: that the one mental state is not immediately induced by the other, that the bodily manifestations must first be interposed between, and that the more rational statement is that we feel sorry because we cry, angry because we strike, afraid because we tremble, and not that we cry, strike, or tremble because we are sorry, angry, or fearful, as the case may be." This view has apparently been held in different forms by Sergi, Richet, Ribot, Münsterberg, and others, and has provoked a storm of controversy.

FIG. 1.



Galvanic reflex to prick stimulus. Record shows heart beats. Below is the record of the Deprez signal marked "key." Time above in fifths of a second.

I shall not attempt to follow the arguments based on introspective considerations, but will turn to those furnished by objective methods. Sherrington attempted a physiological solution of the problem by depriving a dog, so far as possible, of all afferent paths of somatic sensation. He transected the spinal cord in the cervical region and subsequently performed double vagotomy. In spite of the deprivation of organic sensation that was occasioned by these measures the animal showed unmistakable signs of emotion when angered or menaced. The experiment is, as Sherrington recognises, by no means conclusive; all that it entitles us to say is that for the dog in this condition emotional manifestations were confined to the head and neck area, and we have already adduced evidence that changes in muscle tonus are just as much one of the factors of the organic emotional response as visceral and vaso-motor changes. Ward has urged that James's theory is a flagrant ὕστερον [illegible]—a putting of the cart before the horse. [illegible]tion is always the expression of feeling; and feeling, for the subject that feels, has always some objective ground. Emotion is never the reception of impressions, but is always the response to them. Let us see how far a purely objective inquiry as determined by observations of the bodily reactions will help us to settle the question. Fig. 1 is the record of a reaction to a nocuous stimulus, manifested by the galvanic reflex, of a motor voluntary reaction and of an involuntary motor reaction or start. About the last-named reaction—the start—I have little to say; its latent period is very short, about 0·08 of a second. It can be, as Sherrington has shown, elicited as a purely mesencephalic reaction to auditory stimuli in decerebrate animals, when its latent period is about 50 σ. In this case the stimulus was a fainter one, and the latent period is appreciably longer than that found by Sherrington in animals— and this is the rule for any type of start reflex as elicited in man; it is therefore by no means certain that it has the same bulbar origin as the reflex in decerebrate animals. It is not an invariable accompaniment of affective states determined by nocuous stimuli, and for our present purpose we may disregard it. The next event recorded on the photograph is the voluntary motor reaction: the subject was instructed to press a key as soon as he perceived a prick. The latent period is here a normal one of 0·2 second. The third event is the movement of the galvanometer fibre at the beginning of the galvanic reflex. The latent period of this reflex is here 2 seconds. If the galvanic reflex be taken to indicate one of the many bodily responses that go to make up the general state of bodily activity whose sensory equivalent is an affective state then this affective or emotional state is arrived at quite 1·8 seconds after the initial stimulus has been perceived and acted upon.

It might be urged that the galvanic reflex is a response sui generis with a remarkably long latent period, and that the other responses take place more rapidly. The analogy between the galvanic reflex and the time relations of the "cat pad" phenomenon of Luchsinger might prima facie lead us to the same conclusion. The experiment of Luchsinger, it will be remembered, consisted in observing a secretory current from the pad of a cat's foot when the sciatic nerve was stimulated electrically and the latent time of this reaction, measured by Waller in the human subject, is about 2 seconds. The latent period of the plethysmographic response can be measured with a fair degree of accuracy, and in the previous lecture we have seen that its time relations are the same as those of the galvanic reflex. The latency of the alterations of pulse rhythm cannot obviously be determined accurately, but by collation of a large number of tracings I have never found it to be a shorter period than 2 seconds. We have seen reason to believe that the acceleration of the cardiac rhythm is due to removal of the inhibitory action of the vagus, and physiological experiments assign a latency of about 1 second to the vagal reflex.

The latent period of the respiratory changes is similarly incapable of accurate determination, but I have never found it to be less than 1 second. The muscular tonic response in the majority of my determinations had a latent period of about 2 seconds. I have no data as to the latent period of visceral and

The long weary vigil in the first line of trenches and the hardships endured, also the comparatively idle months spent away from the firing-line, have made many of the men unwilling or unable physically to return to their previous employment. Some of them have lost their taste for work, and they clamour, like those who remained at home, for shorter hours of labour. Shortening of the shifts and a change in the hours of work are notable facts of the times. Men no longer go fasting to work at 6 o'clock in the morning and breakfast in the factory at 8 o'clock. They leave home, or ought to, after a comfortable breakfast in time to reach the factory by 7.30 A.M., and this has been to the advantage of employer and employed. Better time-keeping has been the result and there has been less sickness. Shortening of the hours has, in most industries, been followed not by diminished but by increased production and by a rise in wages, but as there is a limit to which hours can be shortened and productive efficiency retained, it is a question whether, in some trades, this limit has not now been reached. It is unwise to work men and women to the last unit of their energy, for not only is work under these circumstances never so good, but fatigue—although the contention is not supported by Dr. Vernon—may become a cause of accident. It is now generally admitted that fatigue is the result of the action upon the tissues of such poisonous substances as carbon dioxide and lactic acid formed by the chemical dissolution of the glycogen of overworked muscles. These bodies act, not only upon the muscular tissue itself and the nerve endings in the muscles, but since they find their way into the blood stream they poison the higher nerve centres in the brain, thus converting fatigue, the outcome primarily of localised changes in the neuro-muscular apparatus, into a general state of the organism, and of these two forms of fatigue, central and local, the central or general fatigue is the more important.

Sir Thomas Oliver then alluded briefly to the effect of fatigue on the blood, demonstrated by Dr. Otto Burkard, of Graz, and after commenting on the problems arising out of compensation for industrial disease, concluded with a few words on

The Industrial Medicine of the Future.

Since industrial medicine has come to stay, facilities will in the future have to be provided to medical students and young graduates to become familiar in a practical manner with its objects. Never were the times more opportune than to-day. The prosperity of a nation is intimately bound up with the health of the people who compose it. Preventive medicine has, practically speaking, swept these islands clear of typhoid fever and considerably reduced the mortality of diphtheria. What it has accomplished on the side of public health it can also accomplish in regard to occupational disease. The die has been cast. There is a psychology of industry just as there is a physiology. Psychology is no longer simply "the science of mind or soul," but "the science of the facts of human nature and behaviour," and there is no department of human activity which offers greater scope for its study and application than industry. Employers no longer regard "industrial hygiene" as something to be turned down on the ground of its interference with labour and the conditions under which it is carried on. They recognise that it introduces into industry just that something with a touch of humanity in it which softens the asperities of labour, makes occupation more healthful, and tends to bring employers and employed into closer touch with each other. Had it not been for "welfare work" carried on during the years 1914 to 1918 the enormous productions of munitions could hardly have taken place, and without it we would have lost the war. Industrial medicine and welfare work go hand in hand. Invention and chemical research tend to make industrial processes, if not more complicated, sometimes more dangerous, as was the case in the early days of the war with the handling of certain high explosives, but the same inventive skill which created temporary dangers showed itself equal to supplying an antidote to them or of finding a substitute. In the ever-enlarging sphere of industrial enterprise, to which the various sciences are contributing, and the needs of the world are calling for, lies the opportunity of Industrial Hygiene.

A MINE MEDICAL OFFICERS' ASSOCIATION ON THE RAND.

MEDICAL service to white workers in most of the gold mines on the Rand is secured by the appointment of one, two, or more whole-time or part-time medical officers by a Mine Benefit Society, to which each worker contributes, and the funds of which are administered by a committee elected by the men themselves. Recreation rooms, library, billiard rooms and facilities for outdoor games are also provided by the Benefit Society, and a hospital is run for the employees of one mine alone or for those of two or three neighbouring mines. The native employees as a rule are under the care of doctors appointed by the proprietors of the mine, and besides staffing the native hospitals these doctors are responsible for supervising the sanitation of the compounds and the hygienic conditions of the native worker. In order to stimulate discussion on the important problems involved in the care of the native, a Mine Medical Officers' Association has recently been formed, its objects being: (1) To study and discuss all problems of special interest appertaining to the work of mine medical officers. (2) To promote and foster friendly intercourse and consequent exchange of views among mine medical officers. (3) To bring to the attention of members matters of interest to them in their special work, by means of periodical publications, &c., as may from time to time seem most advisable. (4) To coöperate in solving administrative and other problems confronting members. Those eligible for membership are medical officers holding whole or part-time appointments in connexion with mine native hospitals in the Transvaal, and such other medical practitioners as the Executive Committee may from time to time invite. The special liability to pneumonia of certain tribes of natives, their protection from scurvy, and the management of epidemics such as that of tropical ulcer which has recently attacked the native workers at one of the mines, are a few of the problems to which the new Association may be expected to give attention.

In the *Medical Journal of South Africa* of March and April 1921, an account of the first meeting of the new Association is given. Dr. A. J. Orenstein reviewed the theories as to the ætiology of scurvy, and spoke of its special interest to medical officers of mines dealing with native employees. In the early days of large scale mining operations scurvy, he states, was prevalent, and though in recent years it had decreased enormously, there had occurred in 1920 in on of the important groups of mines over half the number of cases recorded in that group during the last six years. The figures he gave were as follows:—

—	Cases.	Repatriated.	Deaths.
1915	69	51	2
1916	116	55	1
1917	52	56	2
1918	51	69	3
1919	106	38	5
1920	403	102	16
Total ..	797	371	29

Dr. Orenstein said that the vitamin theory was substantiated by the experiences of medical officers in the Rand. In every instance which had come under his own observation in the last six years an outbreak of scurvy was associated with a diminution of the vegetable ration, or gross overcooking of the same, and in every instance an increase in the vegetable ration, or an improvement in the cooking of same, resulted in the prompt checking of the outbreak. Dr. Marion Delf was continuing work started at the Lister Institute on the effect of cooking on the anti-scorbutic vitamin at the South African Institute for Medical Research.

At the same meeting Dr. S. Donaldson read a paper on the Clinical Side of Scurvy in the Mine Native Labourers; he described two types of case, one of which was much more amenable to treatment by anti-scorbutic remedies than the other. In the course of the discussion Dr. Orenstein expressed his conviction that the condition found in mine natives was not scurvy alone, but was due to a deficiency in all three vitamins. Certain cases had improved rapidly after receiving vitamin B., and others after fat soluble A. had been increased in their diet.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—Will you allow us to make a very urgent appeal for funds to send working girls and women away for a short holiday? Many of those who are hoping to go during the next few weeks have never slept out of London for a single night. We are almost at the end of our resources, and the need for our help is probably more urgent than ever before. Trade depression has resulted in the girls being the main support of thousands of families, which but for their earnings would be on the verge of starvation. The general standard of comfort in the average home is lower than it has been for many years, and the health of the community in the crowded and airless factory districts of London has deteriorated considerably. Nor has it been possible for the girls to save for a holiday as they have done in former years. Good food, rest, and fresh air for a short time will make it possible for many to continue their work through the winter, who would otherwise break down under the strain and privation they have had to bear for so many months, and the short holiday will give them fresh hope and courage. We earnestly ask for subscriptions and donations to be sent to the Chairman of the Executive Committee, Mr. J. F.

glands have a direct influence on the affective responses it is difficult in the present state of our knowledge to bring forward any incontrovertible proofs of this hypothesis. It must never be forgotten that a glandular structure in the normal body is not inert so far as the furnishing of afferent impulses to the central nervous system is concerned.

It may well be that these afferent impulses and not the internal secretions evoked by their activity are the determining influences of the glands on any particular mechanism of response. I was able to obtain records of the secretion of saliva from my own parotid gland by applying a small catheter tube maintained in position by a suction ring over the orifice of the duct. This procedure has been adopted by other observers for the recording of conditioned reflexes produced by the sight of food; I found that nocuous stimuli, if of sufficient intensity, tended to produce inhibition of the saliva flow. The fall of the drops was recorded by allowing them to tilt a tipover key that closed a Desprez signal circuit and thereby recorded on a smoked drum. There is not wanting evidence of the disturbances of the gastric, intestinal, and renal secretions as a response to nocuous stimuli. We have so far seen that the mechanism of all forms of cerebral activity is capable of being recorded in terms of muscular and glandular activity; before attempting to transfer this knowledge to the investigation of neuroses we must consider the constitution of some of the more complicated nervous mechanisms in their barest outlines. In the last lecture I showed a slide (Fig. 7) illustrating a conditioned reflex; you may perhaps remember that the subject was taught by means of a painful stimulus to perform a certain movement and that we noted that when the stimulus was intermitted, whilst the audible sign that had hitherto accompanied it was made, the subject responded precisely as if he had perceived the stimulus. We also noted that the signs of an affective response, as evidenced by the galvanometer, were present when the click of the electric key occurred in the absence of the stimulus. In the language of popular psychology the subject had formed a habit, or in that of physiology a pattern reflex had been conditioned. Now supposing the stimulus had been repeated a requisite number of times, the subject would, at any rate for the first few occasions on which the click of the key was alone given, have found himself utterly unable to control the movement of pressing the signal key. But this movement was in the first instance one that had been acquired as a result of the activity of the discriminatory mechanism of the cortex. It has now ceased to be discriminatory and become independent of the first process of nice adjustment of a specific mechanism to a specific response by the inhibition and coördination of other forms of cortical activity. There is, however, no evidence that the response has ceased to be controlled by the same cortical mechanism which started it. I found in this particular instance that after the first few times the voluntary muscular reaction settled down to a constant latent period of 0·18 second and that later when the conditioned reflex was elicited by a click alone the latent period remained unchanged. Owing to the slow rate at which these particular records were taken the latent periods could not be read closer than to 0·02 second, but the accuracy is sufficient to justify our assumption that the reaction continued to be performed by the same cortical mechanism that had been responsible for its initial manifestation.

Now this statement embodies a very important fact of which the psychotherapist endeavours to make full use. It means that when the reaction had become part of a conditioned reflex and had ceased to be the centre of conflicts between various alternative reflex paths, which conflicts we generally associate with conscious perception, the conditioned reflex still made use of the same cortical mechanism. That is, it still had a direct nexus with all those processes with which it had been originally connected. Therefore by the use of appropriate methods of observation it should be possible to determine what the original associations were when they are no longer objects for the subject's own consciousness.

CONDITIONED REFLEXES IN DAILY LIFE.

Now the greater part of our daily conduct is made up of such conditioned reflexes or habits, and the more effectively they have been established by constant repetition the more difficult it is to interrupt the reflex pattern by some fresh stimulus. We defined one of the attributes of a nocuous stimulus as a tendency to interfere with and impede the normal tendencies of vital activity. There is no more fixed or powerful activity than that of a well-established habit mechanism. A verbal or physical stimulus that impedes the activity of a habit reflex pattern will therefore act as an intense nocuous stimulus, and through the inevitable thalamic mobilisation of the bodily activities to resist such interruptions an intense affective state will be the sensory result. Not only stimuli from outside may tend to impede the activity of the habit mechanisms. Attempts on the part of the subject to interfere with them will equally evoke the generalised bodily response with the corresponding unpleasant feelings. Lastly, the constant occurrence of these reactions, whenever the habit mechanism is interfered with, may in itself condition a new reflex pattern—an active opposition to all attempts to cause the feeling of discomfort by interfering with the primary habit. Such, I believe, is a restatement in the language of objective psychology of the rather clumsy symbolism which the psycho-analyst makes use of; such terms as "the censor" would appear to be unnecessary in this connexion. There is another type of pattern reflex even more potent and more dissociated from the discriminatory mechanism of the cerebral cortex. Unlike the conditioned reflex it has never arisen in the life of the individual from a discriminatory response to a stimulus. This mechanism is an inherited one, and is unchained by some one specific type of stimulus and by no other. Such innate reflexes of a specific type are in greater or less degree common to all the individuals of the same species; these inherited reflex patterns are known as instincts.

INSTINCT REFLEXES.

Now by definition an instinct is an inherited pattern reflex. It is evoked by a specific stimulus and in response to this stimulus the pattern is unfolded. The end-result of the reflex is implicitly determined by the nature of its innate mechanism, and it is a mere matter of chance whether this end-result is ever presented to the subject who owns the reflex. Though by observation we may sometimes learn what the end-result really is, it by no means follows that we shall necessarily do so, and in the case of the lower animals—as when an insect, after laying its eggs, prepares food for larvæ that it will never live to see—it is quite certain that it can never know the end-result towards which the instinct reflex is orientated. Now it is of great importance to the understanding and treatment of the neuroses that we should know whether an instinct reflex has any such relation with other discriminatory mechanisms as may allow us by association methods to determine its true orientation. We may recognise that a certain line of conduct is not substantially in harmony with the environment, that attempts to impede it cause great emotional disturbance, that its origin is obscure and its end-result opposed to the interests of the patient. It is, however, only by tracing some affinity between its mechanism and the nervous system as a whole that we can hope to understand or influence it. In the case of a habit or conditioned reflex this is relatively easy. It arose as a discriminatory response to a certain stimulus—that is, it was once an object of experience and may again be recalled by appropriate methods. But if the instinct be an inherited mechanism, how can its origin be with any certainty deduced from its relation to other mechanisms accessible to consciousness? The problem is a fundamental one, and has presented itself in many forms.

Croonian Lectures

THE OBJECTIVE STUDY OF NEUROSIS.

Delivered on June 16th before the Royal College of Physicians of London.

BY F. L. GOLLA, M.B. OXON., F.R.C.P. LOND.,
PHYSICIAN TO ST. GEORGE'S HOSPITAL.

LECTURE III.[1]

IN the preceding lecture I dealt with some of the forms of response to nocuous stimuli from a physiological point of view. We cannot, however, content ourselves with purely physiological observations. Our patients come to us complaining of certain definite subjective symptoms and our object is to detect the defects of bodily mechanism of which they are the signs. It therefore becomes a matter of urgent importance to determine so far as we can the relation between bodily responses to stimuli and affective states. It is true that we have learnt physiologically to observe only an infinitesimal part of the bodily changes that are associated with affective states; but that small part is, as we have seen, susceptible of quantitative as well as qualitative observation. As a first step we must consider briefly what we mean by an affective state and what relation it bears to sensation.

SENSATION AND AFFECTIVE STATES.

Sensation is defined as an elementary mental process which is possessed of the attributes of quality, intensity, clearness, and duration. Affection is similarly an elementary mental process, but though possessed of the attributes of quality, intensity, and duration it has been denied that it possesses the attribute of clearness. It is said to be impossible to attend to an affection. If we attempt to do so the quality of pleasantness or unpleasantness disappears and we find ourselves contemplating some obtrusive sensation that we have no desire to observe. If we want to get pleasure from a concert or a picture we must attend to what we hear and what we see. As soon as we try to attend to the pleasure itself the pleasure is gone. (Titchener.) Herein lies the pith of the argument for dissociating affection or feeling from sensation. The subsidiary argument that the opposition of the qualities of affective pleasantness and unpleasantness is not paralleled by any of the facts of sensation appears to me to be untrue, or at best unprovable, because we know no more about pure sensation than we do about pure feeling or affection.

It is at this point that objective psychology comes to the rescue. The reason for the apparent difference between affection and sensation has been made clear by neurological investigations, especially by the work of Head and Holmes. Two systems of afferent function exist—the one system reacts to stimuli of a nocuous nature, and the effector organs which manifest its activity are either organs not under the power of conscious effort or else certain combinations of reflexes which cannot be voluntarily activated. The great terminal ganglions for this mechanism are in the thalamus. This system is phylogenetically older than the cortical system. It originates the defensive reflexes by which the body reacts as a whole to nocuous stimuli, whether by glandular, visceral, vascular, or muscular pattern reflexes. There is another system of nervous mechanisms by which appropriately adjusted reflex patterns are combined in response to stimuli not in themselves possessing either nocuous or benign characteristics, and the terminal coördinating centre of this mechanism is in the cortex. Its function is, to borrow the language of Head and Holmes, discriminatory, and this discriminatory adjustment of certain reflex mechanisms to various stimuli is correlated with consciousness.

The two systems are not, however, independent. When the activity of the cortical processes is impeded, by inhibition arising from either external or internal stimuli, an activation of the thalamic system may occur; in other words, the resources of the body as a whole are mobilised to overcome the resistance. Conversely changes of the activity of the thalamic affector organs when they reach a certain degree of intensity stimulate the cortical receptors and we become aware of a change in the common sensation of the body. The consciousness of such a disturbance constitutes what we term an affective state. This reciprocity between the effector organs of the thalamic system and the cortical discriminatory system was already clearly appreciated by Hobbes—"adeo inter se motus cordis et cerebri sunt reciproci." The function of the cerebral cortex has been said to be discriminatory, a certain stimulus or group of stimuli being integrated with a specific reflex pattern activity, but when stimuli arising from the activity of the thalamic system reach the cortex they represent changes taking place in every part of the body. No one elementary group of sensations will be prepotent; we are only aware of a diffuse sensory disturbance. Such appears to be the objective explanation of the origin of the attempt made by psychologists to differentiate between feeling and sensation. When the thalamic activity is of great intensity in response to a maximal stimulus, such as intense fear, certain of its elements may be so intense that they dwarf the remainder and are attended to as an ordinary sensation when their afferent impulses reach the cortex. Thus an absolutely definite sensation of nausea is experienced by some men when under fire, others complain of a burning sensation in the throat, others of palpitation; and it is a peculiarity of the predominant sensations that they may so dwarf those arising from other forms of organic resonance that a man who is not conscious of any great degree of fear simply becomes aware of a sensation of nausea when under fire for the first time. It may not be till after he has gone through the experience on subsequent occasions that he recognises a connexion between his nausea and exposure to danger.

It is in the preponderance of some one such type of reaction, due either to innate or acquired anatomical abnormalities, that we find the explanation of so many of the visceral types of neuroses. In many cases the actual movement of the effector organ rather than its sensory concomitant holds the attention, as in the case of the well-known occurrence of vomiting, micturition, or defæcation as a response to nocuous stimuli. In the last lecture we have seen that the organic response to nocuous stimuli is manifested as activity, and the response to benign stimuli as quiescence, and we are therefore justified in associating activity of the thalamic system with unpleasantness and quiescence with pleasantness. So far as it has been necessary to speak of these sensory concomitants of the bodily reactions I have spoken of them as states of affection or of feeling. From the physiological standpoint I can see no difference between an affective state and an emotion, and I am perfectly willing to use either term indifferently. From what can be gathered from the writings of psychologists it would appear that when certain sensory elements of an affective state sufficiently predominate so as to direct the attention overwhelmingly to their presentation the state is said to be one of emotion; the difference is therefore one of quantity and not quality. I do not propose to enter into any attempt to differentiate the various types of emotions or affective states. Much of the psychological literature on this subject is characterised by that peculiar naïveté with which the scientific specialist too frequently tends to regard life. Our preceding short review of some of the objective changes verifiable as bodily responses to affective which an instinct cannot be recognised as such. Thus to account for the compelling power of the instinctive mechanism that will drive a man into courses of conduct that are directly at variance with his interests in society as at present constituted, we are invited to divest the instinct of its compelling power and to lay it at the feet of an entity termed the "self regarding sentiment" for whose satisfaction we yield to the unprofitable enterprise. There is a flavour of mid-Victorian self-righteousness about this sentiment; it may possibly have been of great usefulness in strengthening the resolutions of conscientious objectors, but the men who sacrificed their interests in the war because they felt that they could not do otherwise had little use for it. The modifications that will be imposed on a primary instinctive mechanism by the pressure of the environment will be incalculable. It is for this reason that in the elucidation of both instinctive reflexes and conditioned habit reflexes their affinities to the affective states are likely to afford a truer if less detailed insight into their nature than any attempt to range them in a tentative scheme of classification.

---

[1] Lectures I. and II. appeared in THE LANCET of July 16th and 30th respectively. The final lecture will appear in a coming issue.

From what has been said of the relations of bodily response to nocuous and benign stimuli it is obvious that I must consistently range the processes of activity that are distinguished as appetites as being nothing other than responses to nocuous stimuli. From the objective point of view such activities are the response to the present situation of pain and not the pursuit of pleasure. The satisfied man can have no appetites. The nocuous stimulus that arouses our activities is not that conditioned by the desired object itself, but by the limitations imposed by the environment that impede the possibility of our satisfaction by its possession. What is true of appetite is true cf desire. As Spinoza remarks, there is no difference between appetite and desire except in so far as the latter implies consciousness. Desire is self-conscious appetite.

SOME NOTES ON

ORIENTAL SORES.

By M. L. TRESTON, M.R.C.S., L.R.C.P. Lond., I.M.S.,
SURGICAL SPECIALIST, INDIAN ARMY.

Mesopotamia may be described as a land rich in mosques, sand, and oriental sores; as regards oriental sores, a better ground for research could hardly be found than that opened up during the conquest of Irak. Few people left the country without having had an introduction to the sore: many regarded the condition as an unavoidable and trifling evil; some even went so far as to be inoculated on one or other limb in the popular belief that one sore confers immunity. Multiplicity of sores was, however, the rule in cases seen. The incubation period varied from three to six months; cases were more numerous during the cold period—i.e., September to April. The causative agent, the L.-D. bodies, could only be distinguished in the earlier sores—the macular and recent ulcerative type, while the veldt diplococcus could be found in most of the older sores. From the position of the majority of sores various biting insects have been cited as carriers—amongst them the ubiquitous sand-fly and the stomoxys—but definite proof on this point has yet to be established.

The type of sore seen varied from the small bluish-red macule, to the large, irregular, thick-margined ulcers, having scabs dotted with pus puncture holes. The sites, in order of frequency were: wrists, hands, forearms, knees, and feet.

Complications.

In most cases oriental sores run a straightforward course, but complications sometimes arise. One of these is of interest, and was observed in some five cases —i.e., about 0·7 per cent. This was a thrombosis of the vein draining the area in which the ulcer was situated. A peculiarity of the thrombosis was its resistance to medicinal treatment. In one case where the sore was situated on the dorsum of the foot, near the outer two toes, the whole of the short saphenous was represented by a hard thickened cord, a section of which showed successive fibrous laminæ within a thickened vein wall. In two other cases the upper reach of the internal saphenous vein was affected, the sore being on the inner side of the knee; of the remaining cases, one was in the right upper abdomen and the other in the right wrist. In all cases the sore was of some months' duration, and in two cases had apparently healed. The thrombosis refused to clear up under prolonged palliative treatment, and surgical interference, which consisted of complete or partial removal of the affected vein, was required.

Treatment Employed.

The following modes of treatment were tried:—

For early sores—macular and early ulceration stage: (1) X ray applications, one Sabouraud's pastille, once weekly—one to four applications; (2) potassium permanganate crystals: the scab was removed, the base of the ulcer cleaned, and the edges packed with the crystals; (3) methylene-blue; (4) crystals of hyd. perchlor. applied as in 2; (5) injections of tartar emetic: intravenous, starting with $\frac{1}{2}$ gr. doses, and increasing by $\frac{1}{2}$ gr. at intervals of four days. A week's interval, when $\frac{1}{2}$ gr. had been given. Maximum dose 4 gr.; (6) ung. ant. tartrate.

Conclusions.

The results of the various modes of treatment led to the following conclusions: (1) For early sores X ray curative, especially of small sores, with slight, early ulceration; (2) for older sores: potassium permanganate, effective in about 50 per cent. of cases. Methylene-blue of doubtful value; hyd. perchlor. crystals fairly efficacious, but too painful; injections of tartar emetic effective in about 90 per cent. These were picked cases—fairly recent sores and situated usually on the face.

The old sore was the least amenable to treatment of the above type, and the large, thickened scab-forming purulent type of ulcerative sore seldom yielded to medicinal measures. In these cases thorough scraping under $CHCl_3$ and ol. ricini dressing, later replaced by a stimulative ointment dressing, gave the best results.

One's conclusions might, in fact, be tabulated as follows:—

(*a*) For the sore in the early stages: (1) X ray applications; (2) crystals of pot. permang.

(*b*) For the sore in the fairly advanced stage: (1) crystals of pot. permang.; (2) intravenous tartar emetic.

(*c*) For the sore in the more advanced stage: (1) thorough scraping under $CHCl_3$, and application of ol. ricini dressing.

(*d*) For sores in the face, other than those in a very early stage: intravenous tartar emetic.

Under thorough treatment most sores healed within a month. A marked improvement was usually observed after the second injection of tartar emetic.

The scar left was of the tissue-paper variety, with radiating lines of pigment from the periphery. The scar tissue rapidly became darker, especially in the oriental.

London.

St. Andrews Institute for Clinical Research.—A three weeks' course of post-graduate study for general practitioners will be given at the St. Andrews Institute for Clinical Research, Fife, commencing Tuesday, Oct. 4th. The course will consist of lecture demonstrations dealing with methods for the investigation of disease in its early stages, and will be supplemented by demonstrations on matters of clinical interest in anatomy, physiology, chemistry, bacteriology, ophthalmology, and radiology. Graduates desirous of attending this course should communicate as early as possible with the Secretary of the Institute, who will send them full particulars, and will be glad to advise them with regard to securing rooms in St. Andrews.

glandular activity, but indirect evidence would point to their being at least equally long. Thus the objective evidence is unequivocal—the stimulus is perceived, differentiated, and acted upon a considerable time before the presentation of the sensory concomitants of the bodily reactions could be experienced as an affective state. In my own case introspection seems to confirm the objective data. Experiences in the line in France were perhaps a little too complex for analysis, but in the streets of London my absence of mind has frequently nearly involved me in a motor accident. In such cases after successfully avoiding the oncoming vehicle I have experienced some 2 seconds later the feeling that we used to call as children "going hot all over." Had the stimulus been less transitory and the motor pursued me instead of avoiding me the continued organic response would on the sensory side have amounted to what we know as a state of fear.

POSSIBILITY OF EXISTENCE OF AN OBJECTLESS AFFECTIVE STATE.

It is of great importance for the understanding of the nature of neuroses that we should determine whether a reversal of this normal sequence of events can take place; that is, can a pre-existing state of bodily activity, which is the physical aspect of an affective state, determine the orientation of cortical activity so that the state of emotion arises first, and then an object is assigned to it? It may be disputed whether an objectless affective state can exist, but there is ample evidence that the existence of the bodily concomitants of an affective state will facilitate the representation of some situation which will then be assigned as its object. Marañon injected a small dose of adrenalin into a sensitive patient, and obtained various subjective sensations which as a rule constitute the syndrome of terror. At times this was noted by the patient himself, who declared: "I feel as if I were afraid, but I am calm." When, however, he supplied an appropriate verbal stimulus by mentioning some source of anxiety to the patient, although such a stimulus would naturally have caused but little reaction under normal conditions, the patient would break down completely in a fit of emotion.

Hitherto I have not dealt with the influence that may be exercised on the response of the nervous system through the agency of the internal secretions.

DISTURBANCE OF ENDOCRINE SECRETIONS IN RESPONSE TO NOCUOUS STIMULI.

The classical experiments of Cannon seem to have demonstrated that states of excitement are accompanied by a hypersecretion of adrenalin, as evidenced both by direct serum tests for its presence and by the occurrence of glycosuria. His brilliant demonstration has been received with great enthusiasm and a far greater rôle has been assigned by the uncritical to the part played by the hormones in the activity of the nervous system than can be justified by observation. It is too readily forgotten that the effector organs of the vegetative nervous system respond to the internal secretions of the adrenals in precisely the same way as they would if acted upon by the vegetative system directly. It is therefore no proof that a reaction is due to the stimulation by an internal secretion, and not to the autogenous activity of the nervous system, to say that the reaction resembles that which is experimentally produced by the injection of the hormone. Swale Vincent has pointed out that there is no evidence whatsoever that adrenalin, for example, is a normal constituent of the blood; indeed, there is much cogent evidence against such an argument.

That under certain conditions of great excitement adrenalin may be present in the blood seems to be fairly well established from the work of Cannon, but were it secreted as a response to stimuli of a less intense and prolonged nature it could only be present in the blood in such minute amounts as to be incapable of initiating the bodily emotional responses. I have conducted a series of observations on my own blood taken before and after the experience of ten minutes' faradisation. In no case was I able to detect any hyperglycæmia as a reaction to the pain stimulus. It is obvious that the painful stimulus was inadequate inasmuch as it neither increased the blood sugar nor produced glycosuria, but the pain was certainly more severe than is likely to occur in the normal experience of healthy life, and it seems legitimate to assume that the ordinary nocuous stimuli of daily life are unlikely to affect the secretion of adrenalin. This criticism applies even more strongly to the internal secretions of the other endocrine organs as a direct response to nocuous stimuli. When we turn to the evidence in support of the direct influence of the internal secretions on the threshold excitability of the thalamic system, we are on surer ground. There is ample clinical evidence of the state of hyperexcitability of patients suffering from hyperthyroidism to stimuli adequate to arouse an affective response. Experimental observations show that the hormone of the thyroid has a marked influence on bodily activity. This hormone has been isolated and identified by Kendal as an indoxyl iodine compound and found by him to raise the rate of basal metabolism 2 per cent. in a man weighing 70 kilos. when administered in a dose of 5 mg.

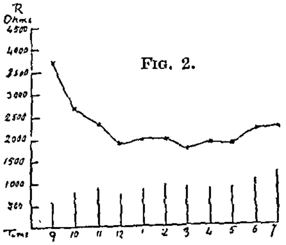


FIG. 2.

Above, curve of diurnal resistance as altered by ingestion of thyroid extract—compare Fig. 8, Lecture II. Below, responses ×2 to maximal stimulus (pistol shot).

I have in a previous lecture dealt with the diurnal variation of the bodily resistance described by Waller, and I showed that there was evidence of a rough correspondence between the magnitude of the galvanic response and the diurnal resistance variation. In order to test the action of ingested thyroid gland on the galvanic response I again made use of this diurnal variation. By taking large doses of thyroid in the early morning I was able both to diminish the mean value of the skin resistance and to mask its diurnal variation. At the same time the galvanic response to uniform sound stimuli of moderate intensity was markedly increased. Fig. 2 may be compared with the record of the diurnal variation of resistance and the magnitude of the galvanic response represented by Fig. 8, in the second lecture. Each diagram represents the mean observations of three successive days. Subjectively, whilst under the influence of thyroid in large doses, I was aware of a marked degree of irritability which lasted throughout the time of the thyroid ingestion experiments, but which appeared to be accompanied by a rather increased power of doing work. I give these subjective observations for what they are worth. That a diminished skin resistance occurs in cases of exophthalmic goitre was shown long ago by Vigouroux. The action of adrenalin in producing effective states has already been considered; but in the absence of any proof of its normal presence in the blood stream we have no right to consider that the normal activity of the affective thalamic mechanism is influenced thereby. There is some direct evidence that the internal secretions of the gonads facilitates the specific affective response to sexual stimuli as shown by the results obtained with implantation of testicular grafts in man and animals suffering from loss of sexual desire. Although there is every reason to believe that the internal secretions of other thrice daily had been tolerated with advantage for a considerable period, the dose had been increased to 15 minims to see if further benefit would accrue. The giving of acid was found to produce, in those cases which showed a rise of blood pressure after its administration, an increase in the concentration of the urine just as the giving of alkalies tends to diminish it.

Definite Divisions of Daily Urine.

At the beginning of our observations the urine examined was taken from an ordinary 24-hour collection, but as we soon realised that as the urinary output for 24 hours is composed of three definite parts, the separate investigation of which offered a greater possibility of discovering how the stress of acid increase fell than the examination of a mere daily average. The three parts into which the daily excretion of urine may be divided are:—

1. *Urine passed on waking in the morning.*—This urine, excreted during the night—that is to say, during a period of mental and physical rest in which neither food nor drink are taken, and whilst the body is maintained at an equable temperature—is the most uniform of the three, and may be called the "rest urine."

2. *Urine excreted during the first waking period after rising in the morning.*—This is normally a dilute urine of low acidity, usually called the "alkaline tide urine," and varying considerably according as the balance of acid and alkali excreted by the organism is well maintained. If the quantity of acid eliminated during the night has not been sufficient to maintain the usual balance of acid and alkali in the tissues this urine will show a degree of acidity in excess of the normal.

3. *Urine excreted during the hours of active life.*—The degree of acidity of this urine, which we may call the "functional urine," is largely controlled by the amount of exercise taken, the quantity and quality of the food and drink ingested, and also by variations in temperature.

Of these three urines the most constant as to quantity, specific gravity, and acidity is, as one would expect, that excreted during the night and passed on waking. The acidity of this urine is a valuable indication of the capacity for excretion of the body at rest, and its acidity should be tested in two directions—for ordinary free acidity, and for the concealed acidity as disclosed by neutralising the buffer reaction of ammonia by the neutralised formalin method.[1] The indicator used is preferably phenol red in a 0·02 per cent. solution. Litmus is far too insensitive in the acid direction to be of any use as a real indicator of the acidity, and phenolphthalein, which was used in much of the earlier work, is found to be just too insensitive on the alkaline side—the kidney is never able to produce a urine alkaline to phenolphthalein. To those desirous of complete accuracy the pH used is 7; the comparator being the standard one sold by Baird and Tatlock for the Medical Research Council for the making of culture media. When the urine is neutralised to pH 7 it is recorded as alkaline. There will still, of course, be the concealed acidity released by neutralising the ammonia by formalin. These details are given as, though they are customary in bio-chemistry, they have not yet become the practice in clinical medicine.

Pathological Effects of Acid Administration.

The first pathological effect of acid administration apparent is a failure on the part of the kidneys to excrete the acid accumulated during the day's activities. This incapacity may be due either to a temporary failure in function, or to a real damage to the renal tissues, which is usually permanent. The first effect of functional failure will naturally be to diminish the "alkaline tide" and bring the urine to a higher and more uniform acidity, so that the three samples will be found to differ much less than usual during the 24 hours. The "alkaline tide" will approach the "rest urine" in acidity and specific gravity or, perhaps more usually, the "functional urine," which generally occupies, on account of the balance of activity by the taking of fluid and certain foods, an intermediate place as regards acidity.

The first indication of a permanent interference with the capacity of the kidneys to excrete acid will be a fall in the acidity of the "rest urine." This has long been recognised as one of the prodromal symptoms of Bright's disease, and is often suggested, in the first place, by the disappearance of previously persistent lithates from the urine, indicating an inability on the part of the organism to excrete excess of acid owing to a structural damage to the acid-excreting mechanism of the kidney. A rise in blood pressure may be observed both in cases of functional failure and of structural damage to the renal tissues. A third indication is the constant passing of a urine of low acidity, especially at night, with a marked increase above normal of the quantity passed in the day, due to a high pressure blood flow combined with diminished capacity to excrete acid. In such cases the three types of urine differ little or not at all in character. The whole 24 hours' urinary output is at a constant "injured maximum."

These conditions are due to an injury to the kidney in respect of its capacity to eliminate acid and are natural enough whether the hypothesis held is the theory of direct excretion or of reabsorption. They are always associated with a urine of constantly low specific gravity. Cases whose renal function is so crippled are curiously "acid sensitive," and a very small dose of dilute hydrochloric acid will raise their blood pressure and induce unpleasant symptoms.

Conclusions.

We recognise that these notes are not by any means complete, as this investigation is really only commencing and is a side issue of a larger investigation on which we hope to report at a later date. We felt, however, in view of Prof. Haldane's lecture confirming our observations of the extreme importance of the acidity of the urine in the regulation of the kidney system, that the importance of the estimation of the renal functions in this direction should be emphasised from a clinical point of view, while the material importance of estimating the blood pressure in all cases where acid was being administered should be reported. In this connexion, had the value of this estimation been known in the two cases in which acid was being given by one of us, in which much injury resulted, the error would have been avoided.

So far, experience has taught us that dilute hydrochloric acid is not, in acid sensitive cases at least, the harmless tonic the books would have us believe it to be, and we are sure that when acid is being administered the blood pressure should always be estimated from time to time, and the urine be occasionally tested for its acid and ammonia relations. We also feel that in cases where an early condition of renal insufficiency is suspected, the "rest urine" should be compared with the "alkaline tide urine" in respect of their relative acidity.

The conclusions arrived at are:—1. That acid largely regulates the amount and character of the urine excreted, by its action on the renal tissue. 2. That this is largely controlled by the increasing acidity of the blood (acidæmia) tending to raise the blood pressure; otherwise the kidneys would not be able to maintain the necessary balance between acid and alkali. This regulation is so delicate that in health the normal variation of blood pressure is not apparent, other causes of increased pressure contributing to its concealment. 3. That when impairment takes place owing to the breakdown of the chemical balance, general acid sensitiveness occurs, and this condition is accompanied by a rise in blood pressure. If the structure of the renal cells is not injured this is not maintained unless the acidæmia continues. If the structure of the cells is injured, the rise of the blood pressure is more or less permanent until other forms of compensation are established. When this structural alteration has occurred acid administration and acid feeding are contra-indicated. Where acid is being administered in doubtful cases the blood pressure should always be observed, to avoid the

[1] Formalin should, of course, be neutralised, using indicator phenol red to pH 7.

To the Atomists, to Heraclitus, and to the Pythagoreans (who never drew a distinction between animal and human intelligence) the problem was never presented, nor do we see any trace of it in the anthropomorphic animal psychology of Plutarch. The conception of a divergence between abstract thought and animal life is implicit in Plato, and the distinction became more definite in the writings of Aristotle and the Stoics. In scholastic thought we find instinct formally recognised as comprehending the totality of animal behaviour and the baser part of human conduct, whilst in Neo-Platonism there is a reversion to the standpoint of the Epicureans. With the wane of scholastic thought the tendency to the anthropomorphic view of animal behaviour has persisted till the present day. Darwin formulated our present knowledge of instinctive behaviour and gave full recognition to its recurrence in man and its evolutionary significance.

The problem as to the relation of instinct and intelligence now becomes a biological one. Those who hold the Neo-Lamarckian doctrine as to the hereditary of acquired characters may consider that instinct is nothing else than a hereditary conditioned reflex—that somewhere in the past a discriminatory action became a conditioned reflex, and by the aid of natural selection such a conditioned reflex has been handed down as an innate part of the nervous mechanism. If an instinct in its earliest stages originated as an act of conscious discrimination its later hereditary form will still show some affinity to the conscious mechanism that first started it, and we might hope that by learning something of its cortical connexions we would arrive at its origin. On the other hand, if an instinct be regarded as a variation preserved by process of natural selection, it is clear that to seek its early cerebral connexion is futile, and if we disbelieve in the heredity of acquired characters the instinct reflex pattern must be unfolded de novo in each generation, and the associations that it may possess will only be such as may have been acquired during the life of the individual. Men of such different schools of thought as Ziegler, Haeckel, Spencer, Wundt, Semon, Ward, MacDougall, and Preyer, adopt the Lamarckian standpoint; Driesch and notably Bergson represent a return to the scholastic view of instinct. For Bergson instinctive behaviour represents a form of activity to which there can never be a psychical correlation in the terms of human practical intelligence. Human intelligence is so developed and so limited as to enable us to adopt mechanical aids to life, and therefore postulates at the beginning of any action a more or less clearly defined conception of what its end is to be. Instinctive behaviour knows nothing of ends; it can only reply to introspection in the words of Luther, "Ich kann nicht anders."

I venture to think that all speculations about the psychical aspects of instinctive behaviour founded on animal observation are of very doubtful value. The supreme act of faith is the attribution of consciousness to our fellow beings, for knowledge of consciousness is never immediately given; but to proceed to speculate about the psychical correlations of instinctive behaviour in insects can hardly be helpful to objective psychology. We must turn to human instincts, and we must obviously select for study of instinctive behaviour an act performed for the first time and from which mimicry and verbal suggestion are excluded.

Expression of the Animal Nest-making Instinct in Human Beings.

Some years ago I observed what has always seemed to me to be a singularly interesting and beautiful instance of instinctive behaviour that fulfils these postulates. If it has been already noted by others I must apologise for presenting it under the guise of a new observation. A primapara about two days before the birth of her child worked very hard at tidying not only all the drawers of her bedroom and boudoir but also her husband's desk. Asked why she did this she said that as she was going to be ill for a long time she wished to have all her own and her husband's things in perfect order. The answer seemed to me to be somewhat inadequate, since as a rule the husband's desk was never interfered with. Some time later the father of several children remarked to me that he always knew when a birth was due, since for a couple of days before it his wife in an excess of energy would tidy every drawer she could find including all his private papers. When I asked him why she did so he said that she gave him the same explanation as I had received in the first case. Now I knew this lady sufficiently well to feel sure that on the occasion of her long absences at her country house, where she spent many months every year, the last thing that would occur to her would be to prepare for her absence by such a minute ransacking of drawers that are as a rule outside her province. I then asked a midwife if this procedure was a usual precursor of childbirth. She said that she had observed it in quite the majority of her cases, and inasmuch as her practice lay among some of the wealthiest people of the country in whose houses such duties as the arrangement of drawers and cupboards are seldom performed by the mistress the phenomenon was all the more striking. Later on when observing the behaviour of a doe rabbit in a breeding hutch I noted that for three or four days before delivery the doe spent her time in a state of frantic activity collecting bits of hay, tossing them up to unravel them, and finally carrying them to the dark compartment at the end of the cage. She was making a warm nest for the expected young. When we find that this nest-making behaviour is universal among the higher apes I think that we are entitled to assume that the drawer-cleaning, sorting, and tidying are the expressions of the animal nest-making instinct.

We have here an instinct untainted by any possibility of mimicry, and since its existence is apparently unknown, free from any complication due to suggestion. The purpose of the reflex instinct mechanism is unknown to the expectant mother, and when her attention is directed to it, and she is asked what she is doing, she casts about for an explanation and evolves one that is not only false but shows no associational nexus to the true purpose of her activity. The distinguishing feature of an instinctive reflex is its compelling urgency. The least delay or opposition to its accomplishment, once it has been aroused by the appropriate stimulus, evokes an intense bodily reaction, and it would appear to be of the imminence of such an explosion of feeling that we speak of as a feeling of compulsion. This feeling of compulsion is the real equivalent of what Bergson terms intuition in respect to instinctive activity. Like the Bergsonian intuition, it cannot be translated into the language of practical thought, nor has it association of a direct nature with aught other than the immediate instinct mechanism. These innate pattern reflexes that we term instincts undoubtedly play an enormous part in the mechanism of conduct. Their recognition in all but such simple cases as I have just now narrated is a matter of great difficulty. They can as a rule be only distinguished from the conditioned habit reflexes by a minute knowledge of the subject's past history such as neither he nor the observer can hope to possess. Much of the vast output of writings on the subject of the instincts that has been characteristic of the last few years loses considerably in value on this account. As I am concerned only with an attempt to show what fundamental knowledge concerning organic disturbances of mechanism can be gained from an objective study of bodily responses and of conduct, I will make no attempt to deal with any system of classification of the different forms of instinctive mechanism. There appears to be a tendency to over elaboration in this direction—Essentia non sunt multiplicanda praeter necessitatem—the "razor" the "doctor invincibilis" has its application in psychological medicine as well as in philosophy. One particularly deplorable move in this direction has been the invention of states or attitudes to take over the very attributes without needling done by native physicians in the veins for the purpose of letting out the "toxic blood," the vein passing over the internal malleolus on the inner side of the foot could always be found.)

Secondly, that relapses were the rule; sometimes even before the completion of the injection of a second patient was completed the first patient, through excessive diarrhœa and vomiting, might be urgently requiring more fluid.

Thirdly, that cases which could be supported until the acute diarrhœa and vomiting had passed, were still in grave danger from suppression of urine. This persisted in some of the cases for six days. The only remedy seemed to be the use of almost continuous "cupping," usually by means of a de Bier's suction glass over both kidneys.

During the epidemic in Foochow in the summer of 1919 kaolin was used by myself with considerable success, but there was difficulty in obtaining a good supply. On my return to Hing Hwa, where cholera was raging, I had no difficulty in obtaining kaolin, as the famous Blanc de Chine clay beds are situated near this district.

The method of administration was somewhat different from Stump's methods. A large supply of half-and-half suspension was placed near the patient and the nurse was told to encourage the patient to take as much as possible. At the commencement large quantities could be tolerated, but as the vomiting and diarrhœa ceased the liquid was refused. In all cases food was withheld for 18 to 24 hours, then rice water was allowed, and later milk and rice water. In all cases rectal lavage was done with kaolin solution thickened until it would comfortably pass through the rectal tube. At first none was returned. Later on much was retained. If the condition of the patient was precarious on arrival at hospital, it was found that subcutaneous bilateral infusion usually restored the patient sufficiently to take kaolin by the mouth. In desperate cases hypertonic salt solution was given intravenously (Rogers), but no such large quantities as we used before the introduction of the kaolin treatment (2 litres). This is shown to be of value by the results obtained by Braafladt with hypertonic saline and kaolin, which were not so good as those obtained with kaolin alone.

Advantages of Kaolin Treatment.

After the introduction of the kaolin method the following differences were noted: if the patient's condition was "fair"—that is to say, that the pulse was perceptible and the patient conscious—the introduction of large quantities of kaolin suspension by the mouth and per rectum would ensure the patient's continued recovery. After two hours all vomiting ceased, a sense of safety had been reached, and the patient usually slept.

In the lighter cases 12 hours saw the cessation of diarrhœa and 24 to 36 hours the passage of urine. In the most critical cases, which required the introduction of saline to bring about an improvement of the pulse, rectal introduction of heavy suspensions of kaolin were commenced at once and had a marked effect in preventing the further loss of fluid. On return of consciousness and during the introduction of the saline kaolin was given by the mouth and was usually retained, while in those cases which vomited it was felt that some kaolin had been deposited on the walls of the stomach which began to absorb the toxic products of the cholera vibrio; the second administration of the kaolin suspension by the mouth was frequently retained or only partially returned.

So the most marked advantages of the kaolin treatment were: (1) simplicity of method; (2) absence of relapse; (3) cessation of loss of fluid; (4) great improvement in the condition of the patient from the absorption of toxins, the patient becoming rapidly free from a general "toxic condition"; (5) early return of the passage of urine; (6) early and rapid convalescence.

In cases treated in St. Luke's Hospital, Hing Hwa, we had a series of 75 cases from one village, situated two hours' journey from hospital, with no fatal results, and this result was obtained in spite of the fact that many of the patients arrived at hospital in a condition of extreme collapse. The mortality of untreated cases at this village was stated by the village headman to be exceedingly high, though I was unable to obtain exact figures owing to the absence in China of any registration of deaths.

Laboratory Experimental Work on the Action and Effect of Kaolin.

In a rabbit fed with 20 c.cm. of a 50 per cent. kaolin suspension, on chloroforming 18 hours later, well-marked traces of kaolin were found over the walls of the stomach, duodenum, and upper small intestine, increasing in amount down the lower small intestine to the cæcum, which was full of liquid contents mixed with kaolin. The colon was full of dry masses of dark brown fæces, which on opening showed white kaolin inside.

In a rabbit fed with 20 c.cm. of a 50 per cent kaolin suspension, and also 20 c.cm. of a 50 per cent. kaolin suspension rectally, chloroformed 42 hours later, the stomach and duodenum distended by a new vegetable meal showed no signs of kaolin, but there were traces on the walls of the upper small intestine which increased in amount to the cæcum, while the transverse and descending colon were full of dry masses of kaolin and fæces mixed.

A further experiment was done to show the microscopical appearance and position of the kaolin in the intestinal tract. A rabbit was fed at 9 A.M. with 20 c.cm. of a 30 per cent. kaolin and water mixture; at 12 mid-day this was repeated, and the rabbit killed at 2 P.M. Sections of the stomach, upper and lower small intestine and large intestine were taken, the gut being stretched on cork rings to prevent retraction on hardening. These were fixed, hardened, cut, and stained with eosin and methylene-blue.

Under a low power the kaolin could be seen lying in a thin line in close apposition to the mouths of the glands. Much of the kaolin had fallen away in the course of preparation. Under a high power it was possible to make out the kaolin, sticking closely to the cells, and in some cases the cells had torn away, adherent to the kaolin layer in process of preparation.

Cultures of cholera vibrios from Guy's Hospital bacteriological laboratory and the Lister Institute were used throughout the following experiments in duplicate. Intraperitoneal inoculations were made through three series of guinea-pigs to raise the virulence. The resulting cultures gave typical pure cholera reactions and were those used in the following experiments. To broth cultures of *V. choleræ* varying strengths of kaolin were added. Later, agar plates were planted from this mixture, and the results given in Table I. were obtained, thus showing that the presence of kaolin in cultures of *V. choleræ* had no bactericidal effect.

NOTES ON THE ADMINISTRATION OF HYDROCHLORIC ACID.

By J. CAMPBELL McCLURE, M.D. GLASG.,
PHYSICIAN TO THE FRENCH HOSPITAL AND TO THE MARGARET STREET HOSPITAL FOR CONSUMPTION, LONDON;
AND
HENRY A. ELLIS, M.B., C.M. DUB.,
ASSISTANT PHYSICIAN TO THE MARGARET-STREET HOSPITAL FOR CONSUMPTION, LONDON.

THE address that Prof. Haldane delivered in Edinburgh on March 4th, on Recent Advances in the Physiology of Respiration, Renal Secretions, and Circulation, has rendered it advisable that we should publish certain observations and deductions made in the course of another investigation which is not yet completed. In this we have arrived clinically at similar conclusions to those recently enunciated by Prof. Haldane—namely, that the regulation of the alkaline balance of the blood, and through it of the tissue fluids, is probably one of the most important functions of the kidneys; and that through this regulation the reaction of the tissue metabolism is largely ultimately controlled. During the other investigation referred to it became necessary to administer dilute hydrochloric acid as a routine procedure in a large series of cases, and we did so under the opinion, apparently generally held, that dilute hydrochloric acid was a more or less harmless drug of tonic properties, though we hardly went to the extent of the following statement, published in "The United States Dispensatory," twentieth edition, 1918, p. 37:—

> *Acid Hydrochloricum dilutum.*—The doses which are sometimes employed are absurdly small. When we remember that the normal acidity of the stomach during gastric digestion ranges from 0·2 to 0·3 per cent. of hydrochloric acid—which would necessitate nearly 2 g. of absolute hydrochloric acid for an ordinary meal—the futility of administering 5 to 10 drops of a 10 per cent. solution of this acid is evident. Dose 10 to 60 minims (0·6–3·75 mils.) well diluted.

We soon had reason, however, to alter these ideas, and we found that we were dealing with a remedy which, although frequently taken without much apparent effect, sometimes produced intense and unmistakable results, and we came to the conclusion that the effect was principally renal in its incidence. Through these observations we arrived at the opinion that the kidneys, equally with the lungs, were occupied in maintaining the alkaline, or what is really the almost neutral, balance of the blood.

This kidney regulation appears to us to be a procedure not entirely simple, but depending on a mechanism under the control of influences both chemical and nervous. Under normal conditions, it would seem that the chemical influence is largely predominant, and that the acid factor is the chief controlling force regulating the general proportions of the output of urine.

Adjustment Effected by Acidity of Urine.

The adjustment effected by the acidity of the urine is much finer than is generally supposed. The variation of the renal functions in health is so sufficient and elastic that the regulator is not apparent, but where there are alterations in the normal condition of the kidneys, not sufficient to be considered pathological, but still sufficient to allow it to be disturbed by moderate excess of the acid factor, the effects may be studied with considerable accuracy. So far as our observations go at present these tend to show that the control of the normal excretion of water by the kidneys is largely a question of acidity. That is to say, where the acidity of the blood is increased, the actual quantity of the urinary flow is diminished, as would naturally be surmised, for the body would desire to retain as much fluid as possible to dilute the acid retained in excess of normal. On the other hand, the attempt to get rid of the excess of acid apparently demands a rise of blood pressure (whether directly or through some intermediary is not known), and this rise of blood pressure, by its compensatory action, tends to increase again the fluid excretion of the kidneys. Where dilute hydrochloric acid is administered this result is apparent, because, as Prof. Haldane says, "The kidney alone cannot deal with this acid at all completely," and the blood pressure is raised, by no inconsiderable amount, where renal inability to excrete acid is at all marked. If acid continues to accumulate against the rising blood pressure the symptoms of acidosis manifest themselves, and the whole organism is materially affected, but this is really a late pathological condition.

Acid Sensitives.

The necessity for taking the blood pressure during our administration of dilute hydrochloric acid soon became apparent, on account of our meeting with a series of cases to which we have given the name of "acid sensitives." The more marked cases of acid sensitiveness show such an intolerance of acid that even a dose of five minims thrice daily is keenly resented. This sensitiveness is sometimes manifested in persons who are apparently perfectly healthy. Intolerance of dilute hydrochloric acid (so far we have not completed the observation by giving other mineral acids) is manifested in two ways: (1) by nausea and vomiting, following rapidly on a dose of the acid—apparently a local intolerance; and (2) by the gradual development of circulatory difficulties accompanied by a rise in the blood pressure—a condition which we have been led to believe is of renal origin. We have had four cases in which local intolerance has been sufficiently marked to make us discontinue the use of hydrochloric acid, and ten cases in which the circulatory disturbance compelled us to interrupt its administration. Among the latter class four cases are worthy of particular mention.

In one, where we had the opportunity for continued close observation, a single dose of 20 minims of dilute hydrochloric acid raised the blood pressure in a few hours, on separate occasions, by 20 mm. of mercury. The other effects noted were flushing of the face, increased rapidity and irritability of the pulse, and before long a sensation of slight giddiness as described by Prof. Haldane in his cylinder experiments, when the acidosis was produced by diminished atmospheric pressure. Incidental to the rise in blood pressure there was, in this case, a considerable diminution in the urinary output, with a rise in the specific gravity and in the acid ratio. It has not been considered advisable up to date to repeat the series of experiments as the injury produced lasted for some days.

In another case the effect was most dramatic. Five minims of dilute hydrochloric acid were given three times in 24 hours and the blood pressure rose from 140 to 240. Subsequent administration of alkalies was followed by a fall in the blood pressure to its original reading after three days. The third and fourth cases were very similar. In each 10 minims of dilute hydrochloric acid had been given for some weeks thrice daily with apparent benefit, but when the dose was increased to 15 minims the patients displayed severe constitutional disturbance with at first a rise of blood pressure much above the normal. The pulse became small and incompressible, while the general appearance of the patients was shrunken and sallow-looking, as in extreme old age. The acid was discontinued and at the same time the blood pressure fell and œdema of the legs appeared.

Where small doses, 5 minims of dilute hydrochloric acid, are administered—following our present usual practice—and continued for some time, there is usually a slight primary rise of blood pressure followed in a few days by a fall, as if compensation had taken place. This condition, however, is not usually reversible. A subsequent rise is not easily produced by a slight increase in the dose, though in the two last-mentioned cases acute symptoms of acidosis with high blood pressure appeared when, after a dose of 10 minims

TABLE V.—*Culture Medium—Alkaline Peptone Water.*

(2 c.cm. injected intravenously in each case as recorded below.)

—	Days' growth of culture.	Peptone medium filtered through porcelain candle.		Bacillary deposit of last column ground in bacillary mill, picked up in saline, and refiltered through candle.		Fatal fluids of above experiments filtered through kaolin filter-beds and filtrate injected.	Above fluids shaken with kaolin, centrifugalised and injected.	2 oz. kaolin placed in ½-litre flask of peptone culture medium.	Control without kaolin.
		Filtrate.	Bacillary deposit.	Filtrate.	Deposit.				
A. Toxins grown from V.C., no passage.	4	—	+ 24 hrs.	..	..	—	—	..	..
B. Toxins grown from V.C., 3 passage.	4	—	+ 12 hrs.	—	+ 12 hrs.	—	—	..	..
	6	..	+ 12 hrs.	—	+ 12 hrs.	..	..	..	..
	11	..	—	—	—	..	..	..	..
C. Toxins grown from V.C., 5 passage.	1	—	+ 8 hrs.	+ 8 hrs.	+ Under 8 hr.	—	—	..	..
	6	..	+ 8 hrs.	+ 8 hrs.	+ Under 8 hr.	—	—	..	..
	11	..	—	—	—	..	..	..	..
D. Toxins from 6 passage (being 5 passage V.C. injected with four-day-old toxins added).	4	—	+ 8 hrs.	+ 8 hrs.	+ Under 8 hr.	—	—	—	+
	6	..	+ 8 hrs.	+ 8 hrs.	+ Under 8 hr.	—	—	..	..
	11	..	—	—	—	..	..	..	..

+ Fatal. — Not fatal.

2. The deposit was scraped from the hollow tube of the candle, mixed with a small quantity of 0·8 per cent. salt solution, and then "killed" by one of three methods: (*a*) heat at 60° C. for an hour; (*b*) Finsen light, one hour exposure; (*c*) chloroform added to the solution in sufficient amount to leave a clear layer of chloroform showing. After shaking the mixture, five minutes killed the *V. choleræ*. (The method of killing the *V. choleræ* appeared to have no marked effect on the results obtained—the "toxins" could be heated at 60° C. to dryness and yet retain their virulence.)

This killed deposit was then injected intravenously into rabbits; 2 c.cm. was fatal, the time varying with the strength of the toxin.

3. The above deposit was then ground in a bacillary mill to break up the bacilli, and after mixing with 0·8 per cent. saline, was again filtered through the porcelain candle.

4. The filtrate was found fatal to rabbits if 2 c.cm. were injected intravenously.

5. The deposit was also fatal to rabbits, being more rapid in its action than the filtrate.

I am greatly indebted to Prof. J. W. H. Eyre, of Guy's Hospital, for his kind assistance in the above experiments.

General Conclusions.

The action of kaolin is two-fold: (1) Mechanical; (2) adsorptive.

1. *Mechanical.*—The administration of such large quantities of kaolin as are used in the treatment of cholera almost fill the bowel, and the passage of this mass through the bowel must enclose and carry with it a very large number of bacilli. It has, however, no bactericidal effect, and this fact calls for energetic action in the destruction of fæces in all cholera cases treated by this method. The fact that the kaolin forms an adherent coating to the walls of the bowel point to its usefulness in ulcerative forms of colitis, though in these cases the rectal method of administration in the form of enemata and long-tube lavage would be preferable owing to the possibilities of errors of digestion arising, after long administration, due to the adsorptive properties of kaolin for ferments.

2. *Adsorptive.*—This, the chief function of kaolin, is very marked: its extremely fine state of division lends itself to that end. From the above experiments it is clear that, at least in the case of cholera, and probably in diphtheria, ptomaine poisoning, bacillary diarrhœa, and general toxic conditions, kaolin has a wide range of use. In cholera, the first result of its administration is the cessation of vomiting. This seems to be due to the adsorption of toxic bodies in the upper alimentary tract. This is followed by cessation of diarrhœa and consequent loss of fluid which is caused by the presence in the bowel of irritant substances of a toxic nature. These being adsorbed by the kaolin cease to act as an irritant, and consequently the improvement of the patient is rapid and maintained. The presence of a layer of kaolin on the walls of the intestinal tract would appear to act partly as a filter-bed and prevent the transmission of toxins to the patient. The adsorptive action of kaolin does not appear to be chemical.

Professor Bayliss has pointed out that kaolin is an electro-negative colloid, which sign may become changed by allowing it to adsorb ions of opposite sign to itself (Bayliss, p. 72); this, I take it, occurs in the small intestine.

I am indebted to Professor Russ and Mr. Clark (of Middlesex Hospital Cancer Research Department) for the following fact (experiments were made after Hardy's method, *Journal of Physiol.*, xxxiii., p. 289): Cultures of cholera vibrio in an alkaline medium gave a definite electro-negative sign. So the adsorption of cholera toxins by the kaolin may be explained by the electrical reaction between the two, and the failure of the toxin to reach the circulation may be explained by the electro-static attraction of the suspensoid kaolin for the cholera toxin, which thus forms one component of a Helmholtz double layer. Professor Bayliss has pointed out that sodium chloride diminishes electro-negative charge, in accordance with Gibbs's principle; this may be the explanation of the marked difference in treatment of cases of cholera which have had saline injections preceding the kaolin treatment, to those treated only by kaolin.

THE LATE DR. VICTOR DONALD ORR LOGAN.—Dr. Logan died at St. Mary's Hospital, London, last week from injuries received through being knocked down by a motor cycle in Bayswater-road. He graduated M.B., Ch.B. Edin. in 1909, and was a temporary Captain, R.A.M.C. Formerly he was resident medical officer at St. Mary's Hospital, Plaistow, to the Sussex County Hospital, Brighton, and to the Prince of Wales Hospital, Tottenham. At the time of his death he was in practice at Liverpool.

danger of overdose. Overdose is also indicated by the "alkaline tide urine" approaching the "rest urine" in character.

Since hearing Sir Almroth Wright's lecture on Acidosis delivered at St. Mary's Hospital subsequent to these notes being compiled, we have come to the opinion that the reason why, during treatment with acid, a rise in the blood pressure is reversible—i.e., followed by a more or less similar fall, while this subsequent fall in blood pressure is not easily reversible—is because an acidosis may be transferred to the tissues, the acidæmia thus being changed into a histo-acidosis, and this causes a fall in the blood pressure. If a histo-acidosis be established it is not easy to raise the blood pressure again, because of the difficulty either of raising the acid content of the blood above that of the tissues or of reducing the acidity of the tissues below that of the blood, the fluid pressure thus persisting towards the tissues, while the balance is against the blood. Such a hypothesis would explain what occurred in the two cases referred to above, in which acidæmia took place.

In these cases œdema and a very considerable fall of blood pressure occurred after the discontinuance of the acid and the condition was not readily reversible. The administration of the alkalies did not remove the œdema, although following on very small infrequent doses of acid the œdema disappeared, and there was a slight rise in blood pressure. This sequence of events would seem to support the idea that an acidæmia had developed into a histo-acidosis.

THE ACTION AND USES OF KAOLIN IN THE TREATMENT OF ASIATIC CHOLERA.[1]

BY RONALD R. WALKER, M.D., B.CH. CAMB.

POSSIBLY the earliest mention of cholera is in the time of the Yellow Emperor of China, circa 1500 B.C., when five general "body conditions" were described. The Ganges bed in India is, however, generally regarded as the home of the disease, and in late historical times, epidemics in 1500 and 1700 A.D. are on record. In 1817 and 1837 there were world-wide epidemics. In every case the infection followed lines of travel—e.g., caravan routes, pilgrimages, lines of ships, &c. Between 1817 and 1823 this plague spread from India through China and as far west as Egypt. During 1826–27 Europe became infected, and thence, via England, Canada and the U.S.A. From 1837–93 Europe has had successive visitations resulting in a death-rate in Russia in one year of 800,000, and in Hamburg of 8600.

In the year 1883 Koch discovered the cholera organism, which he called the comma bacillus or cholera spirillum. This spirillum is a small organism 1·5–2 μ in length, curved on one axis and provided with a single flagellum which causes it to be highly mobile. The bacillus grows freely in alkaline broth or on alkaline agar. It stains readily with weak carbol-fuchsin, and solutions of the culture give a rose-pink colour reaction on the addition of pure sulphuric acid; according to Grieg, true cholera vibrios are non-hæmolytic. Agglutination tests against a high titre anti-cholera serum will differentiate between the true cholera and paracholera or El Tor vibrios.

The disease in man is characterised by general systemic disturbance. Vomiting, profuse watery diarrhœa, muscular cramps, cold clammy condition of the surface, suppression of urine, are the general characteristics. The onset is sudden as a rule, and in the most virulent infections a condition of cholera sicca occurs, where the patient dies before the diarrhœa has set in.

Bolus or Kaolin Treatment.

Treatment has been directed to meet all conditions which occur. Potassium permanganate, opium, saline injections, subcutaneously and intravenously, hypertonic solutions of saline (Rogers) have been used with considerable effect. It was, however, during the Balkan epidemic at the close of the Balkan War, 1913, that Stump's bolus treatment (bolus alba) was tried at Nish by Dr. Victor Kulme[2] with remarkable results. Bolus alba, or kaolin (China clay), is aluminium silicate, $H_4Al_2Si_2O_9$, a salt insoluble in water, with crystals of 1 μ in length in a fine state of division. This salt was in use in early Roman times, and was also used by the natives of the Orinoco. It has also been employed in diphtheria in Germany, as a powder insufflated on the fauces and tonsils, and also a mixture internally. It has also been used in ptomaine poisoning with success (Mutch), also in dysenteries, summer diarrhœa of children, and its use is indicated in the treatment of sprue and toxic conditions. The general effect of the salt seems to point to the absorption of toxins. By the use of this salt Kulme claims that the mortality in the cases treated was reduced from 60 per cent. to 3 per cent. The method of preparation was as follows: A suspension was made of equal amounts of water and kaolin, the kaolin being stirred into the cold water—i.e., 100 g. kaolin to 250 c.cm. aq. Half-pint doses of this suspension were taken half-hourly for the first 12 hours, the second 12 hours several glasses were taken, according to the patient's condition. Vomiting soon ceased, the pulse improved, and the patient slept.

During the summer of 1919 China was visited by a severe epidemic of cholera, and Dr. Louis Braafladt,[3] of Tsinanfu, has given the result of the use of kaolin The method of administration was somewhat different from Kulme's; and his treatments and results are as follows:—

1. Hypertonic saline treatment, after Sir Leonard Rogers—mortality 22 per cent. Convalescents discharged on eighth day.
2. Kaolin and hypertonic treatment—mortality 29 per cent. Convalescent patients discharged on the sixth day.
3. Kaolin treatment only—mortality in 35 cases one patient (this patient died of gangrene of uterus after miscarriage). Convalescent patients discharged after four days.

All these patients had true cholera vibrios isolated during their stay in hospital. In cases of the Asiatic cholera treated in Foochow at the American Red Cross hospital when first opened no definite hard-and-fast line of treatment was maintained. Cases were treated by continuous subcutaneous injection of normal saline, with administration of potassium permanganate by the mouth until the motions became green. Hypertonic intravenous saline injections (Rogers) were given in amounts up to three litres or until the blood pressure became normal. Dextrose was added in some cases to the intravenous solutions.

Whatever method was used, some features of the disease remained constant:—

First, that although the patient on arrival might appear moribund, being cold, rigid, and with imperceptible pulse, the introduction of saline could usually be relied on to produce return of consciousness and a greatly improved pulse. With the hypertonic intravenous solutions a rigor of great intensity could be looked for before the end of the introduction of the second litre. This, however, was disregarded and the saline was continued until the blood pressure had attained the normal. (A point of interest was noted in the treatment of these cases—namely, that when no superficial vein of the body could be demonstrated suitable for the introduction of the saline, through the extreme loss of fluid, or through the

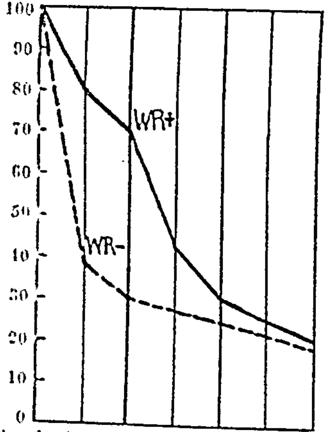
* Wassermann reaction positive (+) or negative (–) on admission.

ship between the attendance of 203 cases of latent syphilis and their Wassermann reaction was analysed; in 139 cases the Wassermann reaction was positive on admission, in 64 it was negative. (See Chart 4 and Table II., cols. 6 and 7.) As a remedy an attempt has recently been made at the infirmary clinic to keep the patients in ignorance of the result of the Wassermann test by using symbols instead of words. Sooner or later, however, they learn, directly or indirectly, the meaning of the symbols. It is therefore absolutely essential that patients should be taught to realise the necessity of attending for blood tests regularly for a long period after cessation of active treatment.

CHART 4.



The chart shows 203 cases of latent syphilis, demonstrating that cessation of attendances is much greater in patients with a negative Wassermann reaction on admission than in those with a positive. (See Table II., cols. 6 and 7.)

4. *Other Factors Influencing Attendance.*—Various other possible factors were considered, but as their influence was not studied statistically, mention only will be made of them; they include the following: 1. Ignorance or callousness—the type of patient who states that he ceased to attend because, his symptoms having disappeared, he "didn't feel anything from it," so he "thought he was all right." 2. Patient's lack of financial interest in his treatment or cure. In my opinion this factor is of considerable importance, but it is acknowledged that there is much to be said for free treatment.

The Letter Card as a Remedy for Absenteeism.

The deplorable state of affairs as regard attendances revealed above has to a great extent been remedied by the adoption of a system of sending letter cards to recall absentee patients. The results have been very satisfactory from the medical officer's point of view. One must admit that in certain instances the employment of letter cards is resented by patients and tends to drive them to other clinics where they are not used. On the other hand, the fear of receipt of a letter card has a very salutary effect in maintaining the regularity of attendances of others. The effect of these letter cards and the relative value of sending one, two, or three cards is seen in Table III. It will be observed that 44 per cent. of the absentees attended on receipt of one letter card; a further 9 per cent. on receipt of a second letter card; and a further 1·5 per cent. on receipt of a third letter card. Thus the attendance of over 50 per cent. of the absentees was secured by this means. It would appear that the majority of the remainder, who had either given the wrong address on registering (8 per cent.), or who had apparently quietly ignored the letter cards (35 per cent.), could only be reached by legislative means. While they "play the game" by

Filtration of suspensions of *V. choleræ* were then made through varying thicknesses of kaolin deposited on silk, as given in Table II., thus showing that cholera bacilli can pass through kaolin.

Agar tubes were prepared with kaolin mixed in the agar in varying amounts. It was found that the presence of kaolin had no effect on the growth of the cholera bacillus.

As far as the above experiments go, it is clear that the presence of kaolin in the bowel can have no other than a merely mechanical effect on the cholera vibrio itself. This mechanical effect, however, may be instrumental in sweeping out a very large quantity of active cholera vibrios, and it should be remembered in using this treatment that the disinfection of the stools is essential; also that it is quite possible that many of the patients return home as cholera carriers.

Preparation of Toxins.

Half-litre flasks of alkaline peptone water were used, incubated at 37° C. for periods of 4, 6, or 14 days. The above medium was filtered by means of an exhaust pump through a porcelain candle. The filtrate was sterile, shown by planting on culture media. The hollow tube of the candle was scraped to remove the deposited bacilli, which, mixed with normal saline, were heated at 60° C. for an hour. Both the filtrate and the saline emulsion containing the dead bacilli were tested as follows:—

Pulp was spread thinly over a perforated plate and 100 c.cm. of a 10 per cent. kaolin suspension poured over this bed. The above liquids were filtered through by means of a vacuum pump. It was found that no indol reaction was obtainable with the filtrates obtained. Commercial indol, on the other hand, filtered through this bed. Tests were made as shown in Table III.

TABLE III.

1. Formalin and strong sulphuric acid	No colour with filtrate.
Filtered commercial indol solution and above reagent	Blue colour.
With unfiltered toxin solutions ..	Blue colour.
2. Glyoxalic acid, Strong sulphuric } and filtrate ..	No reaction.
" " and indol solution	Red.
" " and toxin solution	Red.
3. Nitric acid and filtrate	No reaction.
" " " indol solution ..	Red.
" " " toxin solution ..	Red.
4. Sod. nitro-prusside (fresh sol.) and filtrate ..	No colour.
" " " (fresh sol.) and indol solution	Violet, changing to green-blue.
" " " (fresh sol.) and toxins	Violet on addition of acetic acid.
5. Filtrate extracted with benzol and No. 4 test applied	No colour.
Toxin extracted as above gave characteristic indol reactions.	
6. Paradimethylamido-benzaldehyde, Alcohol, HCl., Potass. persulph. (equal parts) } and filtrate..	No colour.
" " and indol sol.	Pink.
" " and toxin ..	Pink.

The above series of tests were made as the fact of the "toxin" being held back by the filter bed while indol solution came through pointed to the possibility that the toxin giving indol reactions is not a true indol, but a larger molecule which is held back by the China clay filter, while the commercial indol, which has a small molecule and is in solution, can get through.

A further series of experiments was made to test the absorptive power of kaolin for "indol," as found in the *V. choleræ* toxin-peptone water culture fluid. Week-old *V. choleræ* toxin was taken and well mixed with equal weights of kaolin. Of this mixture 1 c.cm. was withdrawn every five minutes for an hour and a half and tested with Ehrlich's indol reagents. A standard colour series was made with commercial indol solutions of dilutions up to 0·0001 g. per c.cm. added to Ehrlich's reagents, and it was found that after centrifugalising 1 c.cm. of kaolin and toxin suspensions at five minute intervals no variation in the indol colour index was obtained, thus showing that the suspension of kaolin in *V. choleræ* toxin cultures had *no absorptive action on the indol in the culture.*

A further series of experiments was made to test the action of kaolin on ferments. Rennet and trypsin were used. (Table IV.)

TABLE IV.

	Result.
Rennet and milk	Coagulation.
Rennet centrifugalised and milk ..	Coagulation.
Rennet shaken with kaolin and milk..	Some delay in action.
Rennet and kaolin shaken at intervals *for half an hour.* Centrifugalised: clear liquid added to milk.	Considerable delay in action.
Rennet filtered through kaolin bed and filtrate added to milk.	No action.

The same experiments were performed with trypsin, and the digest of gelatin plates used as indication of action of ferment. The same results as above were obtained and it was found that trypsin filtered through kaolin beds had no digestive action on the gelatin plate. It was found that 3 c.cm. of a 10 per cent. kaolin suspension caused rapid death in a rabbit if injected intravenously. Death was caused by deposit of kaolin on valves and walls of the heart and subsequent clotting of the blood. Six c.cm. of a 1 per cent. suspension had no apparent effect on the rabbit. On post-mortem examination 24 hours later no kaolin could be detected in the blood. Intraperitoneal injections of 10 c.cm. of a 20 per cent. kaolin suspension in a guinea-pig caused death in 20 hours. Post mortem: signs of peritonitis. Masses of kaolin were present everywhere in the abdomen. The lower surface of the diaphragm and the omentum were thickly plastered with kaolin. Slide preparations were made of the mesentery and omentum, but it could not be demonstrated that the lymphatics were packed with the salt, though its presence, adherent to the cells, was obvious everywhere.

Toxins.

The culture used in the experiments given in Table V. was one from a fatal case of cholera in India. The vibrio was non-hæmolytic, agglutinated well, and gave typical reactions of a cholera vibrio. Half-litre flasks of alkaline peptone water were used. These were sterilised three times with an interval between sterilisation to remove all spore-bearing bacilli. The resulting toxins were examined at 4, 6, and 14-day growths. It was found advantageous to have wide-necked flasks so that as large a surface area as possible might be presented to the air. The resulting bacillary growth was moved each day by shaking, when it fell to the bottom of the flask and a new growth appeared. To obtain a virulent culture for growing the following method was adopted.

A rabbit was inoculated intra-peritoneally with one tube of 24 hours' growth of the strain mentioned above. On chloroforming in three hours' time it was found that all signs of the cholera vibrio had disappeared, and no growth was obtainable. Therefore passaging was then done through a series of five rabbits, each being killed two hours after infection, the growth cultivated on agar for 24 hours and the whole culture injected again. By this method a more virulent organism was obtained, a tube culture of which would kill a rabbit in 20 hours. One loop of culture killed in five days with progressive wasting.

A. Toxins were grown from cholera vibrio ..	No passage.
B. " " " " " ..	3 passages.
C. " " " " " ..	5 "

Finally:

D. Toxins were grown from the five passages *V. choleræ* injected into a rabbit, with *the addition of some of the four-day* toxins grown *from the five passages V. choleræ.*

The four strengths of "toxic fluids" were then investigated as follows:—

1. The toxic fluid was filtered through a porcelain candle by means of an exhaust pump. The filtrate, which was clear, was injected intravenously and intraperitoneally into two rabbits with no fatal results. Amounts up to 4 c.cm. were used.

stage of the disease, and, if necessary, treatment should be by intrathecal as well as intravenous injection.

In general paralysis the vessels are affected long before the appearance of symptoms. The nervous system is involved in 40 per cent. of congenital syphilitics, and signs usually appear before adolescence. In all diseases of the spinal cord the cerebro-spinal fluid should be tested for the Wassermann reaction. The speaker expressed the view that it is very likely syphilised arteries recover if treatment is begun early.

Discussion.

Prof. E. S. **REYNOLDS** (Manchester) approached the subject from the clinical standpoint, and commented on the protean character of the symptoms of visceral syphilis; in any condition which does not run a course typical of a recognised organic disease syphilis should be suspected. In a doubtful case examination of the eye and skin not infrequently reveals signs of old syphilitic disease. Syphilitic lesions are more often multiple than single. In the speaker's opinion the majority of cord diseases are not syphilitic. Too much reliance must not be placed on the Wassermann reaction; a positive result in the cerebro-spinal fluid does not necessarily mean nerve syphilis, and not 10 per cent. of all cases of syphilis develop either tabes or G.P.I. Spasticity is always very marked when it occurs in syphilitic disease. The chief syphilitic affections of the spinal cord are pachymeningitis, meningo-myelitis, acute myelitis, gumma, and Erb's spinal myelitis.

Dr. **JOHN COWAN** (Glasgow) showed lantern slides illustrating syphilitic disease of the heart and aorta. The diffuse myocardial fibrosis occurring in the early stages, gumma, diffuse fibrosis resulting from coronary disease, or the occlusion of a coronary orifice by syphilitic aortitis and early syphilitic disease of the aortic valve, are quite characteristic, but in many chronic diseases the cause is not recognisable. Any cardiac affection may be syphilitic in origin, he said, but its recognition in a particular case often depends on finding evidence of syphilitic infection, old or recent, in other organs. The Wassermann reaction is a good servant but a bad master, and should be used only as an aid to diagnosis. It is not a specific test from a serological point of view; a positive result is of value, but a negative is useless. Cardiac manifestations as a rule appear late, and only about 75 per cent. give a positive blood Wassermann. A case of aortic disease without mitral involvement arising in a patient between 30 and 50 years of age is most likely syphilitic, whereas aortic disease associated with a mitral lesion in a man between 20 and 40 years old is probably rheumatic. The majority of cases of heart block, myocardial disease and auricular fibrillation are not syphilitic in origin. Though too much must not be expected from anti-syphilitic treatment in cardio-vascular syphilitic disease, it is urgently required. Large doses of salvarsan are contra-indicated; moderate doses combined with long courses of mercury and iodide give the best results. No amount of treatment will remove thrombus from a vessel or restore dead tissue, but it is possible to improve the endarteritis.

Dr. **A. G. GIBSON** (Oxford) considered the diagnosis of syphilitic aortitis. Cases may be quite latent, an unsuspected patch being discovered post mortem. The "effort syndrome" may induce substernal pain and tenderness on pressure due to stretching of the aorta, an X-ray examination of which shows a wide shadow with an indefinite outline. Anginal pain may be due to coronary obstruction. Paroxysmal tachycardia may be the condition to attract attention. Aortic regurgitation is the best known sign and the easiest to recognise. Aortitis may cause a variety of abdominal symptoms, but in each group pain is induced when the blood pressure is raised, there is tenderness on deep pressure over the aorta and an increased width of shadow; the atheromatous aorta shows no such enlargement. Some cases do well on a solution of mercury and potassium iodide, and small doses of salvarsan repeated over a long period; salvarsan in ordinary doses is contra-indicated.

Dr. **IVY MCKENZIE** (Glasgow) stated that he had seen two cases of syphilitic nephritis amongst 1500 cases of syphilis during the last eight years. Both occurred during the "secondary" stage, and in each the albumin and blood cleared up with the disappearance of the rash. In the "outdoor treatment centre" vascular symptoms are rare, whilst nervous complications are relatively common—in the last 500 cases treated 40 returned with symptoms referable to the nervous system. He related a case which post mortem showed gummatous infiltration of the right ventricle, death having taken place six weeks after the onset of symptoms. He considers angina is due to aortic disease irritating the vagus and sympathetic nerve endings in the arterial wall.

Dr. **ISAAC HARRIS** (Liverpool) showed electrocardiograms from two cases of syphilitic myocarditis. In the case of a man aged 41, who was admitted to hospital with symptoms suggestive of gastric ulcer, the electrocardiograph revealed a want of conduction in the right branch of the bundle of His. His blood Wassermann was positive, and there was a history of syphilis contracted 20 years previously. Potassium iodide removed his symptoms and restored the cardiograph to normal in three weeks. He maintains that syphilitic and non-syphilitic disease of the heart may give rise to the same symptoms and signs, that iodide is very effective in localised disease of the myocardium, but mercury is more efficacious in generalised arterial disease.

Dr. **JOHN EASON** (Edinburgh) dealt with the anæmias of syphilis. The blood picture of "pernicious anæmia" was found in an infant 14 months of age, whose blood Wassermann was positive; the mother's serum also gave a positive reaction. He advocated the Wassermann test in all cases of anæmia in infancy both on the mother and the child. The blood picture of "pernicious anæmia" may also occur in the "secondary stage" of the acquired disease. He quoted three cases seen during the war, two of which recovered completely; in the fatal case, a man aged 36, mercury was of no benefit in treatment, and at the post-mortem the liver contained no free iron and no spirochætes were found in the spleen or bone-marrow. In the "tertiary stage" an anæmia with enlarged spleen simulating Banti's disease may occur. In one case resembling "pernicious anæmia" hæmosiderin was found in the liver and spleen.

Sir **CLIFFORD ALLBUTT**, in reply, briefly referred to angina pectoris. It is a very important symptom of aortitis, he said, whether syphilitic or not, and indicates disease of the tunica adventitia. The pain is often very trifling, and may be only a sense of oppression across the upper chest, with or without pain referred down the arm.

THURSDAY, JULY 21ST.

Asthma and Allied Conditions.

The opening paper was read by Sir **HUMPHRY ROLLESTON**, who stated that the diseases in the group of "toxic idiopathies" are hay fever, asthma, urticaria, angio-neurotic œdema, Henoch's purpura (or purpura with abdominal symptoms), eczema, and some other forms of acute dermatitis, some cases of acute gastro-intestinal disturbance, and some forms of croup. Doubtful examples are migraine, epilepsy, cyclic vomiting, and possibly gout. The various theories as to the causation of asthma were passed in review, and the evidence in favour of these diseases being anaphylactic phenomena considered; when this subject was discussed at the Birmingham meeting ten years ago the accepted view was that asthma was a "reflex neurosis," only the opener of the debate, the late Dr. G. A. Gibson, suggesting that "modern theories of anaphylaxis may in the future aid us in our understanding."

Do we now attach too much importance to hypersensitiveness in asthma to the neglect of a reflex side? In discussing ætiology, the predisposing factor of heredity was emphasised; with a strong family history a sensitiveness to several different proteins often appears. Whether hypersensitiveness may be

THE INADEQUATE ATTENDANCE OF THE MALE SYPHILITIC OUT-PATIENT.

BY R. E. ROBERTS, M.D. LIVERP., B.Sc., D.M.R.E., D.P.H.,

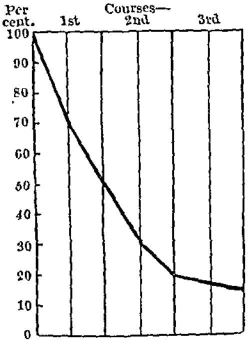
REGISTRAR, X RAY DEPARTMENT, ASSISTANT PATHOLOGIST AND SENIOR CLINICAL ASSISTANT, V.D. DEPARTMENT, LIVERPOOL ROYAL INFIRMARY; HONORARY RADIOLOGIST, WALLASEY VICTORIA CENTRAL HOSPITAL AND BIRKENHEAD BOROUGH HOSPITAL.

DURING an investigation at the Liverpool Royal Infirmary venereal diseases clinic, begun in 1918, on the effect of various forms of anti-syphilitic treatment upon the Wassermann reaction (which investigation has been continued since 1920 for the Medical Research Council), it was observed that the great majority of patients failed to complete their treatment, or even part of their treatment; in fact, only about 25 per cent. attended sufficiently regularly, even for a short period, to render their records of the slightest value for the investigation in hand.

An attempt has therefore been made to analyse carefully the attendances of new patients during the year beginning July 1st, 1918, in the hope of ascertaining the factors governing non-attendance and also of discovering remedies.

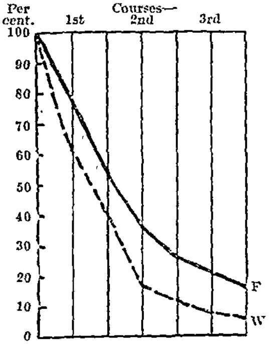
In Table I., and in the other tables and charts, the "first course," extending over three months, consisted of 6 intravenous arsenic injections and 8 intramuscular mercury injections, followed by 1 month's rest. The "second" and subsequent courses varied according to the patient's condition, but extended in each case over a period of 3 to 4 months.

CHART 1.



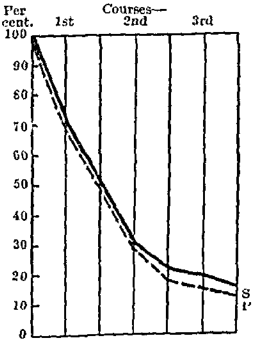
The chart shows attendances of 517 new cases of primary and secondary syphilis, demonstrating the rapid falling-off in attendances after admission.

CHART 2.



The chart shows the attendance of 197 patients with fixed local abode and 121 "wandering" patients, demonstrating that their fixity or otherwise of abode has a moderate influence upon subsequent attendance. (See Table II., cols. 8 and 9.) F, "Fixtures"; W, "Wanderers."

CHART 3.



The chart shows attendances of 109 cases of pure primary and 145 cases of pure secondary syphilis, demonstrating that the severity of the disease has very little influence upon the patient's subsequent attendance. (See Table II., cols. 1 and 3.) P, Primary; S, Secondary.

It will be seen from Table I. that 801 new patients suffering from syphilis were admitted during the 12 months. (Patients who were subsequently "transferred" to other hospitals or clinics have been omitted from the table as their inclusion would vitiate the results of this inquiry.)

Attendance of New Patients for Treatment and Observation.

In Table II. the attendances of the various classes of patients have been expressed in percentages. A glance at the table will reveal the rapid falling-off in attendances of every type of patient.

The patients who ought to attend for the longest period are those admitted in the primary and secondary stages; for they have, as a rule, received little or no previous treatment, and should attend for treatment or observation for periods varying from two to four years before they can safely be struck off the register as "cured." Their attendances are recorded graphically in Chart 1. We see that of these cases only 50 per cent. reached the end of their first course, 20 per cent. reached the end of their second course, 14 per cent. reached the end of their third course.

Consideration of Some Factors Influencing Attendances.

1. *Influence of Fixity of Abode upon Attendances.*—In a port such as Liverpool it is too readily assumed that those who fail to attend are chiefly seafarers, and their absence is therefore unavoidable. To ascertain if this were so new patients were divided into two groups: (*a*) "Fixtures"—those having an occupation which allowed of a permanent abode in the district; (*b*) "Wanderers"—those, such as seafaring men, bargemen, commercial travellers, variety artistes, &c.—whose occupation entailed a more or less wandering existence. The attendance of the two groups are given in Chart 2. The curves show that the nature of a man's occupation does not play the large part in his attendance behaviour one might anticipate. They incidentally demonstrate that less than 20 per cent. of patients with fixed local abode reached the end of their third course—a very discouraging discovery.

2. *Influence of Severity of Syphilitic Symptoms on Admission upon Attendance.*—It was expected that a man admitted suffering from generalised (secondary) symptoms would be more alive to the possibilities of the disease than one suffering from localised (primary) symptoms only, and consequently attend better. The attendances of patients admitted (*a*) in the primary stage, (*b*) in the secondary stage were therefore ascertained. (See Chart 3 and Table II., cols. 1 and 3.) It is seen from the chart that one's expectations were not realised, for there is very little difference between the attendances of the two groups of cases.

3. *The Influence of a Negative Wassermann Reaction upon Attendances.*—It was discovered that one of the commonest causes for the cessation of attendance was the patient's belief that a negative Wassermann reaction indicated recovery. When absentee patients who had been recalled by letter cards were interrogated, the majority replied, "My blood test was negative, so I thought I was cured." The relation-

micturition; muscular pains may be very misleading. One man had severe pain in the hand for four days, and a week later typical symptoms developed. The onset may simulate apoplexy. Few diseases have such a variety of symptoms; some only are of value in differential diagnosis. It is an infective process with the symptoms of such, but in addition there are those referable to infiltration of the central nervous system with lymphocytes, the perivascular dilatation, œdema, neuroglial proliferation and infarction. These pathological changes are situate more especially in the mid-brain, extending into the crura or pons, and often to a wider area, including the cord. All ages and both sexes are attacked, but especially middle-aged adults in the colder months of the year when influenza is common. There are very few instances of contagion. The disease has been produced experimentally and transmitted in rabbits and monkeys. The organism, which probably resembles that of poliomyelitis, has been cultivated. There is no direct relationship between acute poliomyelitis and encephalitis lethargica, but the question of the connexion, if any, between influenza and lethargic encephalitis is undecided.

The laboratory is at present of little help in diagnosis. The type of the disease seen in 1918 having altered considerably, the French symptom-complex of lethargy, fever, and ocular paralysis is seldom seen now. In diagnosis the following points should be considered: mode of onset, presence of prodromal symptoms, and fever. Of special symptoms the most important are ophthalmoplegia of central origin and acute onset, which may appear when the acute stage of the disease is passed; diplopia lasting a few days only is seldom met with in other conditions; nystagmus, varying in amplitude and rapidity, and not necessarily occurring in the direction in which the eyes are moved; blurring of vision, due to paralysis of accommodation; conjugate paralysis of upward movement of the eyes; lethargy or drowsiness; the mask-like face is only seen in this disease and in paralysis agitans; Korsakow's psychosis may be met with and various forms of involuntary muscular movement. In treatment very little advance has been made. Netter's method of producing a fixation abscess with turpentine has sometimes a striking result.

Dr. **DA FANO** (London) showed lantern-slides illustrating granules surrounded by a halo in nerve cells which he and Dr. Helen Ingleby have described in the central nervous system in fatal cases of the disease. The occurrence of these haloed granules has been confirmed by Dr. Bernard Shaw, and similar bodies have been found in rabies—a disease in some respects resembling encephalitis lethargica. He referred to a correspondence with Dr. A. H. Booth, of Victoria, who has seen actively motile granules in the blood and gland juices in cases of encephalitis lethargica, but Dr. Da Fano had been unable to stain these bodies in slides submitted for the purpose. Details of an acute case of encephalitis which died in three days, diagnosed during life as cerebral hæmorrhage, were given.

Dr. C. H. **MELLAND** (Manchester) said encephalitis lethargica was not the cerebral type of poliomyelitis, though the two infections were probably closely related. The majority of cases not being lethargic now he suggested "epidemic encephalitis" as a better name, or on account of the protean nature of the symptoms "encephalitis polymorphica." The study of the epidemiology of the disease is very imperfect, as many of the slighter cases are not recognised, and it is possible that these mild cases play an important part in the spread of infection. They show very few symptoms, and lethargy is as a rule conspicuous by its absence. He related a series of cases in which the first diagnosis proved incorrect—a woman of 26 whose illness began suddenly with ptosis and vertigo and drowsiness. She was thought at first to be syphilitic. One year later slight weakness of the internal recti alone remained. In a young boy whose illness began with severe headache a diagnosis of typhoid fever was suggested. He developed paralysis of the internal recti and double optic neuritis. It was three months before there was any improvement in the paralysis or neuritis, and a boy of 16 whose illness began with headache and weakness of the legs walked with a limp three months later. The importance of minor symptoms was insisted on, and a series of slight cases of the disease was briefly referred to.

At the termination of Dr. Melland's remarks Lord **DAWSON** declared the discussion closed, and the consideration of Renal Efficiency Tests (see report of Section of Pathology and Bacteriology) was proceeded with.

SECTION OF SURGERY.

WEDNESDAY, JULY 20TH.

This section, over which Prof. **RUTHERFORD MORISON** presided, opened with a discussion on

Acute Pleural Empyema.

Mr. **HENRY WADE** (Edinburgh), in introducing the discussion, said that so great was the incidence of this condition, and so wide was the experience in its treatment, that our practice was tending to become standardised; nevertheless, he felt confident that many new lines of thought might be brought up at that meeting.

In dealing with the pathology of acute pleural empyema, there were two factors to be considered—viz., "the seed and the soil." The commoner infecting organisms were the pneumococcus and the streptococci, and there were three paths of infection: (1) the blood stream; (2) the lymph stream; (3) direct extension. In his opinion by far the commonest of the three was the direct mass infection from a focus in the lung spreading outwards till it lay beneath the visceral layer of the pleura. He considered that in this respect the process was exactly similar to the mode of causation of peritonitis following acute appendicitis. If the condition was untreated, a natural cure might result by the localisation of the infection by pleural adhesions, and the dissection of the pus either outwards toward the skin, inwards toward the bronchi, downwards through the diaphragm, and the eventual spontaneous evacuation of the pus either through the skin of the chest wall, through a bronchus, or through the skin at a greater distance—e.g., as a psoas abscess. There was another rarer result—viz., calcification may occur in the empyema cavity, giving rise to a large calcareous plate beneath the ribs.

But inasmuch as the patient is only too frequently overwhelmed by toxæmia before such a natural cure, and because such a cure takes a long time, leaving, perhaps, endless troublesome complications in its train, we find abundant justification for surgical intervention in every case. In the past the usual procedure, notwithstanding local differences in technique, has been incision and drainage, but Mr. Wade was not satisfied with the present technique, which he considers has the following dangers: (1) the operative danger, which is largely an anæsthetic risk; (2) the dressing danger, which is that of mixing the infection; (3) the convalescent home danger, which is the failure to obtain full expansion of the lung.

In thinking over the subject in the search for an ideal operative technique, he was led to compare the treatment of acute infective processes in two serous and one synovial cavity—viz., the peritoneum, the pleura, and the knee-joint. He considered that the analogy between the three was so striking that the principles of treatment for the peritoneum and the knee-joint should be applicable to the pleura also. During recent years there has been a revolution in the treatment of sepsis. He would point two examples of this:—

A.—*The peritoneum.*—The following are the phases through which technique had passed: (1) the use of strong antiseptics to destroy the infection; (2) flushing out the whole cavity with saline; (3) gentle clearing up of infected material, with multiple tubes; (4) the removal of the primary focus, with drainage by one tube or possibly without drainage at all. This evolution in treatment has been brought about by three factors. In the first place, the clinical surgeon attending, let secrecy be the rule; but when they cease to attend and resist all efforts to reclaim them, let the law step in.

TABLE III.—*Illustrating the Effect of sending* 1, 2, *or* 3 *Letter Cards to recall Absentee Patients for Treatment or for Wassermann Test.*

In the early part of 1920, 219 absentee cases were written for; of these:

			%
No. of absentees written for once	133		—
„ „ „ „ „ „ twice	46		—
„ „ „ „ „ „ thrice	40		—
	219	=	100
No. who attended on receipt of 1st letter card ..	96	=	43·9
„ „ „ „ „ „ 2nd „ „ ..	20	=	9·1
„ „ „ „ „ „ 3rd „ „ ..	3	=	1·4
Letter cards returned:	119	=	54·4
(*a*) Wrong address given when registering ..	18	=	8·2
(*b*) Removed from address given when registering	5	=	2·3
No. who ignored letter cards	77	=	35·1
	100	=	45·6

Summary and Conclusions.

1. An analysis of the attendances of 801 new cases of syphilis admitted to the Liverpool Royal Infirmary venereal clinic during one year beginning July 1st, 1918, demonstrated that the attendance of these patients was extremely unsatisfactory. Of new cases of primary and secondary syphilis 50 per cent. reached the end of their first course, 20 per cent. the end of their second course, and 14 per cent. the end of their third course. If this state of affairs were allowed to continue it would be a menace to the public health and a waste of the public money.

2. Apart from failure to attend through ignorance, callousness, and lack of financial interest in treatment, the effect of three factors upon attendance has been specially considered by statistical methods. (*a*) Fixity of abode: This has a moderate influence; for absenteeism of seafaring men and other "wanderers" was only about 10 per cent. to 20 per cent. greater than that of the "fixtures." (*b*) Severity of symptoms on admission: This has very little influence; for the absenteeism of patients with primary syphilis was only about 2–3 per cent. greater than that of those suffering from the constitutional symptoms of secondary syphilis. (*c*) Positive or negative Wassermann reaction: This has a great influence upon absenteeism; of 203 cases of latent syphilis the attendances during the first three months were roughly twice as good in those admitted with a positive Wassermann reaction as in those admitted with a negative reaction. Obviously great stress should be laid in the instruction to patients that a negative Wassermann reaction does not mean a cure.

3. The sending of letter cards is a partial but valuable remedy for absenteeism, resulting in the recall of half the absentees. Thus 19 absentees were written for, 43·9 per cent. attended on receipt of the first card, 9·1 per cent. on receipt of the second, but only 1·4 per cent. on receipt of the third. 8·2 per cent. gave the wrong address when registering.

I am indebted to Dr. Ernest Glynn, Professor of Pathology, to whom this investigation was indirectly due, for much helpful criticism; and to Mr. F. P. Wilson, surgeon in charge of the Venereal Department, Royal Infirmary, for allowing me free access to the records employed.

HOSPITAL SUNDAY FUND.—On July 28th at the Mansion House, the Council of the Hospital Sunday Fund met to make their awards for the year, Mr. R. Holland Martin occupying the chair. The Fund amounted to £101,920, and the Council decided to distribute £100,170 to hospitals and dispensaries, the chief awards being as follows: Charing Cross Hospital, £2460; Great Northern Central Hospital, £2515; Guy's Hospital, £4655; King's College Hospital, £1320; London Hospital, £12,300; Middlesex and Convalescent Home, £1130; Royal Free Hospital, £2735; St. George's Hospital, £3710; St. Mary's Hospital, £2715; St. Thomas's Hospital, £3520; University College Hospital, £2115; West London Hospital, £2200; Westminster Hospital, £2220. Several other institutions received sums of over £1000; the Fund was smaller by £10,000 than last year.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT NEWCASTLE-ON-TYNE.

SECTION OF MEDICINE.

WEDNESDAY, JULY 20TH.

THE first session was given up to a discussion on

Visceral Syphilis,

with especial reference to the cardio-vascular and central nervous systems.

Prof. THOMAS BEATTIE (Newcastle), the President, in his introductory remarks recalled the last discussion of this subject in 1893. In those days syphilis was largely untreated, and in this town—seaport, military depôt, and industrial centre—they saw a large number of cases. In the army a man with venereal disease was either in hospital or in the ranks; if he had syphilis he was only treated in hospital until the primary and secondary stages were passed. When he became a reservist the strain of physical labour, added to the imperfect treatment of his syphilis, led to the frequent development of aneurysm, general paralysis, tabes, transverse myelitis, and peripheral neuritis, and more rarely syphilitic disease of the pleura, lung, liver, and pancreas. At the present time syphilis is detected by the blood test in many cases in which it was not previously recognised because there was no history of previous disease. Modern treatment can eradicate the disease. In the future the incidence of these conditions will be diminished and fewer cases of visceral syphilis will be seen, as there is less chance of these complications occurring in treated cases.

Sir T. CLIFFORD ALLBUTT, who opened the discussion, first dealt with the histology of syphilis, insisting upon the importance of the vascular changes, which are strictly comparable in "primary" and "tertiary" lesions—the disease is a disseminate lympharteritis. The rapidity of generalisation of the virus via the lymphatics was emphasised—a syphilitic septicæmia is soon established, characterised by fever, rashes, and anæmia; some of the rapid deaths reported in early syphilis after the injection of salvarsan may be due rather to syphilitic than arsenical poisoning. He said that the disease when it attacks the arteries begins in the adventitia, and the change is quite different from that seen in athero-sclerosis. It arises in the aorta as a periaortitic lympharteritis, which tracks through to the intima, in which it may spread upwards or downwards to the aortic valve and coronary orifices. If a valve cusp is affected it may be severed from its attachment. Atheroma rarely ends in aortic regurgitation, syphilitic aortitis frequently does, and is often combined with coronary disease. In 70 per cent. of cases of syphilis microscopical examination shows that the aorta is affected, and it may be at a very early stage. Angina pectoris may be an early symptom of this involvement. Syphilitic disease of the ventricles is not common; there is no direct evidence of a diffuse fibrosis save as a consequence of coronary disease. Certain cases of pulmonary fibrosis and bronchiectasis may be syphilitic; a diffuse induration of the lung either at the root or at an apex may simulate pulmonary tuberculosis, and the two infections may exist together. Bronchitis in a syphilitic subject should be carefully watched; gumma of the lung is rare. Syphilitic lesions of the alimentary canal below the œsophagus are seldom met with except in the rectum. Gumma of the kidney is rare, and it is doubtful if there is a true syphilitic nephritis. The central nervous system may be infected very early in the disease, long before any clinical symptoms arise, and this especially in those cases which show little "secondary" manifestation. Here the essential change is also a panarteritis. The Wassermann reaction in the cerebro-spinal fluid may be positive while that in the blood is negative, and a positive test may be found in the cerebro-spinal fluid in the absence of symptoms. Sir Clifford Allbutt urged that lumbar puncture should be performed at every the prognosis was good. He was glad to note that the general trend of opinion was toward early closure.

Method of Approach in Appendicitis.

Sir HAMILTON BALLANCE (Norwich) read a paper on the best method of approach in cases of acute appendicitis. The method described was used in those cases where the diagnosis was clear, for if there was any doubt a mid-line subumbilical incision was imperative. He considered that there were the following fundamental factors to be observed: (1) The shortest possible route must be ensured; (2) fullest possible view to be obtained; (3) surrounding viscera to be disturbed as little as possible; (4) removal of appendix in every case with very few exceptions. He showed a series of slides illustrating the steps of the operation which were as follows: (*a*) skin incision, well outside rectus, parallel to Poupart's ligament; (*b*) division of external oblique, half muscle and half aponeurosis; (*c*) division (in line of incision) through internal oblique and transversalis; (*d*) division of peritoneum; (*e*) search for appendix to inner side of cæcum, then to outer side, and then behind; (*f*) pelvis always explored for pus. He claimed that the pelvis could be easily drained through such an incision, and that he did not find ventral herniæ resulting.

In the discussion which followed Mr. HAMILTON RUSSELL, Mr. RUSSELL COOMBS, Mr. E. W. G. MASTERMAN, Mr. SOUTTAR, Mr. MCADAM ECCLES, and Mr. MAMOURIAN spoke, and in nearly every case disagreed on the grounds that the incision would weaken the abdominal wall and herniæ result.

Sir HAMILTON BALLANCE, in reply, said that even if ventral herniæ should follow they were very easily closed.

Intussusception.

Mr. EDINGTON submitted an analysis of cases of intussusception under his care during the years 1908–14:—

Sex.

Male, 27. Female, 8. (Male 77 per cent.)

Age.

Under 1 year ..	24	4 to 5 years ..	1
1 to 2 years ..	5	10 years	2
2 to 3 years ..	1	70 years	1
3 to 4 years ..	1		

Types.

Ileo-cæcal ..	7	Colic	5
Cæcal	6	Ileo-colic	4

Combined.

Ileo-colic Ileo-cæcal	3	Enteric Ileo-colic	3	Enteric Ileo-colic Ileo-cæcal	3

Gangrene .. 6.

Ætiology.

Meckel's diverticulum	2	Mobile colon ..	2
Enlarged glands ..	4	Nothing abnormal ..	27

Results.

Recoveries, 21 = 60 per cent. Death, 14 = 40 per cent.

Prognosis.

Enteric far the worst.

THURSDAY, JULY 21ST.

Mr. A. M. MARTIN (Newcastle) was in the chair, when a discussion on

Compound Fracture of the Thigh and Leg

was opened by Mr. NAUGHTON DUNN (Birmingham), who reviewed the treatment of compound fracture of the femur before the war. He recalled the gradual adoption of operative treatment in place of manipulation and splintage. The commission instituted by the British Medical Association before the war laid down as one of its findings that operation afforded the best means of obtaining a perfect functional result. The war soon caused an alteration of opinion, largely because of the gross sepsis present in war wounds. Many types of old splints were tried and many condemned, and it was left to the Thomas knee-splint to dominate the whole situation. It became installed as a part of the medical equipment of the most forward units, and its use saved many a life from shock. He quoted a series of 500 cases of fractured femur in his experience, of which only 11 cases had as much as half an inch shortening, and these were considered a disgrace.

Now the results of compound fracture were: (1) shock; (2) infection; (3) want of primary union; (4) secondary bone infection.

Bearing in mind these results, he had laid down regulations for the treatment of compound fractures as follows:—

1. Immediate fixation in a Thomas splint, as in the war.
2. Suspension of the splint in transport.
3. Treat shock, which according to Gray was aggravated by hæmorrhage, cold and pain, loss of fluids, particularly alkaline ones. He always used intravenous gum acacia or blood transfusions in all cases in which the blood pressure had fallen below 85 mm. For acidosis, alkalies intravenously and by mouth.
4. Operative treatment. Under gas and oxygen anæsthesia he opened up the wound, excised all damaged tissues, and closed with drainage wherever possible. If badly infected he left wide open and did a secondary suture later. He then set the fracture, ensuring correct alignment, immobility, and lack of compression of the limb.

He maintained that all these factors were fulfilled by using a Thomas knee-splint for all fractures of the femur excepting those in the upper third. These resulted in flexion and abduction of the upper fragment, and should be treated in a Robert Jones abduction frame or in a Sinclair net-bed.

In fractures of the shaft he pointed out that the position of deformity likely to occur was outward angulation and sagging at the site of fracture, and internal rotation of the lower fragment. He avoided these by putting up in a Thomas splint bent to 160°, with extension, the foot being held in a Sinclair foot-piece fixed on with glue. He suspended the splint by a weight and pulley to a Balkan frame. He advised early movement at the knee-joint with frequent X ray examinations. Usually union was sound by the tenth week and massage could be started, and then he got them up in a caliper splint, but he did not allow the bone to take the weight until X rays showed trabeculation of the new bone at the seat of fracture.

Fracture of the Tibia and Fibula.

Mr. Dunn said that in these cases the deformity was a valgus one, combined with failure of restoration of the normal tibial curve leading to flat-foot and genu recurvatum. If the fracture was of such a nature that it could not be replaced, and especially if there was a fracture involving a joint, operation must be undertaken. Other complications which might occur were limitation of movement due either to extra-articular fibrous changes or intra-articular adhesions. All these troubles may be avoided by early fixation in a Thomas knee-splint with early elimination of sepsis. In addition, a flexion frame must be fixed to the splint to allow of a range of movement in the knee. If stiffness occurred he insisted that graduated splintage was far superior to forcing rapid movements, and he emphasised the teaching of Sir Robert Jones—viz., that if ankylosis is inevitable each joint has its most favourable position.

In dealing with the sequelæ of these compound fractures of the lower extremity, he pointed out that the persistent sinus may be the most troublesome. These were due to: (1) the retention of a foreign body; (2) a septic bone cavity; (3) potential sequestrum not yet separated.

In these cases it was most difficult to decide the most favourable time for interference. He personally considered that it was essential that the patient should be in good general health, have no local reaction, no temperature, and no history of a severe reaction after previous operations. Even then he gave a prophylactic dose of sensitised streptococcal vaccine. He then proceeded to define the extent of the septic acquired, or whether its appearance for the first time in adult life is merely a "delayed action," was considered; constant contact, as in bakers with flour proteins, does appear to induce hypersensitiveness, but it is improbable that the condition arises de novo from absorption of foreign protein via the subcutaneous tissues or a damaged mucous membrane. Hypersensitiveness may first appear after an acute infection, and serum sickness may occur only in patients who have a transmitted natural hypersensitiveness to horse serum. Asthma begins in the majority of cases before the age of 45; sensitiveness to some protein is more likely to be revealed by a positive skin test in cases arising in the young than in later life, and when the attacks begin in infancy multiple sensitisation, particularly to food proteins, is not infrequent. The value of positive skin tests in the diagnosis of hypersensitiveness to protein is shown by the success of treatment—desensitisation by injection of the offending protein, avoidance of a food protein, or vaccines—based on the information thus provided. What significance should be attached to a negative reaction when symptoms suggest a specific sensitisation? The known forms of protein causing hypersensitiveness are very numerous—130 are employed at the New York Hospital, and there are probably still many unrecognised. In some cases giving a negative skin test bacteria play a prominent part.

The importance of prophylaxis and treatment by specific desensitisation by the hypodermic or oral administration of the offending protein was considered; a proportion of cases is improved by autogenous vaccine prepared from the sputum. The importance of the elimination of all septic foci was insisted on. On non-specific lines treatment by intramuscular or intravenous injection of peptone was referred to, and finally treatment by drugs.

Discussion.

Dr. JOHN FREEMAN (London) maintained that asthma is a product of hypersensitiveness and a nervous reflex; foreign protein is but one link in the chain. In hay fever the protein factor is the more important, but some nervous reflex is often the immediate exciting cause. An attack may be induced in susceptible persons by suggestion, bad news, strong light, emotion, &c. Reflex, protein, hereditary taint are all factors, and there are probably others. Bronchial asthma is in the same category as other "toxic idiopathies." Asthma and hay fever tend to run in families, but a summation of stimuli is sometimes required to induce an attack—e.g., horse asthma and hay fever may be combined—and such a patient only has asthma during the pollen season if he approaches a horse. The skin reaction given by grass pollens is enormously greater than the food protein skin tests. Infections play a very important part in the production of asthma, the focus may be anywhere in the body, and the exciting protein may be the bacterium, its toxin, or derived from tissue destruction. In testing the skin reactions it is found that the pollen of each kind of flower is different, whereas that of grass is common to all. Dr. Freeman described the technique of the skin reaction, and demonstrated various proteins dried on filter paper. In performing the test a small abrasion of the skin is produced as in Jennerian vaccination, the skin wetted with saline or weak alkali, and the protein-containing filter paper applied for 15 minutes.

At a later stage of the discussion, at the request of the PRESIDENT, Dr. Freeman added that he considered the ophthalmo-reaction to be very valuable as a means of detecting hay fever cases. There is no sensitiveness to grass pollen unless the patient gives a positive skin or conjunctival reaction. In treatment the dose of pollen injected must be cut down during the season.

Dr. MACKENZIE WALLIS (London) had found that a patient with intermittent hydrarthrosis and psoriasis which showed a definite periodicity was sensitive to her own synovial fluid. The fact that many cases of asthma showed a definite periodicity induced him to investigate the disease on similar lines. A case of periodic tobacco-smoke sensitiveness was described, and one due to egg albumin, in which an attack was induced by the application to the hands of an egg-containing embrocation. He had tested the skin reaction of 500 cases of asthma. About 40 per cent. show a positive reaction; the majority react to the pollens, followed by meat and fish proteins. A positive protein skin test is obtained in some cases of epilepsy—one case was mentioned in which a patient had a fit after eating white of egg in confectionery. The proteins for test purposes do not keep well in solution. In patients sensitive to food protein the omission of the offending article from the diet was the best treatment.

Mr. FRANK COKE (London) considered asthma an anaphylactic phenomenon. Many gastro-intestinal symptoms unsuccessfully treated by surgery are in reality due to hypersensitiveness to food proteins, and illustrative cases were quoted. It is possible the symptoms are due to shock produced by protein split products; histamine shock is very like anaphylactic, and the symptoms of anaphylactic and histamine shock vary in different animals. It may be that histamine is concerned in the production of asthma, and he would say that asthma is the result of poisoning by protein or protein derivatives. A short course of some food may be a cause of sensitisation to it; prolonged contact is another—e.g., bakers to flour—asthma in such cases may be due to the action of a specific ferment elaborated by the organism as a defence against the particular foreign protein.

Dr. A. E. GOW (London) stated the majority of patients with bronchial asthma that he had tested gave a positive intradermal test with Witte peptone, but not all individuals in whom the test is positive are asthmatic. While the best results of peptone treatment are obtained in those cases which do show a well-marked intradermal reaction, some of the others may be benefited; the stronger the reaction the smaller should be the initial dose for intravenous injection. Some cases of asthma and hay fever are extremely sensitive to intravenous injection of Witte peptone; transient urticaria and angioneurotic œdema occasionally follow. Peptone to many of these "toxic idiopathies" is a dangerous drug, it should not be given during a paroxysm, and its indiscriminate use is likely to bring discredit on what is, in certain cases, a valuable remedy.

At a later stage in the discussion Dr. Gow, at the PRESIDENT'S request, replied to certain questions raised relative to peptone therapy, and outlined a course of treatment.

Dr. JOHN F. WALKER (Southend-on-Sea) expressed the opinion that information obtained by general practitioners in these conditions should be collected in some way for examination by experts.

Dr. WARREN CROWE, Dr. JAMES CHALMERS, Dr. JOHN STENHOUSE (Toronto), Dr. D. G. HAMILTON, and Dr. GREENFIELD also spoke before Sir HUMPHRY ROLLESTON replied.

In the afternoon a demonstration of the Skin Tests in Asthma was given by Dr. MACKENZIE WALLIS in the Pathological Department.

FRIDAY, JULY 22ND.

Encephalitis Lethargica.

A joint discussion with the Section of Pathology and Bacteriology occupied the first part of the third session. Lord DAWSON OF PENN presided.

Dr. EDWIN BRAMWELL (Edinburgh), in the opening paper, gave a brief summary of the present state of knowledge of the condition. It was a disease new to living man, with widespread incidence and serious mortality. As the lesion is not confined to the brain, and lethargy is not a constant symptom, the nomenclature was criticised, but there seemed to be grave objections to "epidemic encephalitis." The onset varies; more commonly it is gradual with well-marked prodromal symptoms, less frequently is it abrupt. Common prodromata are lethargy, drowsiness, headache, tremors, diplopia, insomnia, difficulty in frame over pulley A then down to pulley B, thence to C, back to D, and thence over the bed-end to the weight (B and D are pulleys on the same axle-pin). The foot end is blocked up, and the leg rests in pillows.

Pulley A is attached to the crossbar of the Balkan, and B and D to the upright. Diagram B shows the lines of forces acting in a parallelogram, the resulting force being in the direction of the femur (the longitudinal force being twice that of the uplift).

Mr. Russell claimed that perfect alignment was obtained and maintained, however much the patient moved. So convincing was it, that if at the end of 24 hours the shortening had not been overcome, he was very much on the "qui vive," and any imperfection in position after 48 hours was an absolute indication for operation. He believed the Thomas knee-splint to be invaluable for transportation, but once the patient was in bed, it was unsound in principle, lacking in comfort, and unsuccessful in functional results. He showed conclusively that there is no injury to the ligaments of the knee-joint in extension via the tibia, for the extension does not affect them but only the long muscles reaching from tibia to pelvis. Heavy weights were not necessary, a fact proved by the fractures of the humerus, in which the weight of the forearm, &c., was more than sufficient, and if uncontrolled would cause appreciable separation of the fragments.

Sir HAMILTON BALLANCE thought the idea an excellent one, but personally favoured the Thomas splint; but he was of opinion that the factor of the greatest importance was the extension; the splint was of little import. He was in agreement with Mr. Russell that extension through the knee-joint had no deleterious influence on the joint structures. The amount of extension was greater in civil work than military because of the destruction of muscle in the latter. He used 15 lb. in wounds, 20-25 lb. in civil cases, and he preferred weight extension to fixed extension, and his experience of glue was unsatisfactory, owing to skin irritation. Calipers were efficient but quite unnecessary in civil practice.

Mr. ECCLES called for a definite ruling on the treatment of open fractures and on the value of antiseptics. He asked how Mr. Russell prevented external rotation of the lower fragment, and if he had any pressure complications from the sling.

Mr. DUNN, in reply, said that he was encouraged by the large majority in favour of the Thomas splint. He disagreed with Mr. Tubby, whose cases might have left Egypt in a satisfactory condition, but they did not stand transportation well. He personally found no difference between fixed and weight extensions.

Mr. RUSSELL, in reply, could not agree to the use of splints. With his apparatus nursing was easier than with a Thomas splint. External rotation was perfectly controlled. He quoted a case of his own with both femora fractured and treated by his method, which was up in ten weeks, away to convalescent home 12 weeks, rejoined at end of fourth month, and went through three more years of active service. The Thomas splint may be good for fractured tibiæ, but for the femur it was unsound in principle, as it added weight to the limb and depended for its efficiency upon pressure on the tuber ischii, and, therefore, if efficient, it was uncomfortable, and if comfortable it was inefficient.

The Bone Graft.

Mr. MARCUS MAMOURIAN (Ashton-under Lyne) read a short paper on bone-grafting. He said that although bone-grafting was now recognised as a most important advance in surgery, yet the fate of the graft was unknown or disputed. Ollier and Macewen were still the exponents of the two lines of thought. He was of opinion that the graft acted merely as a stimulus to bone formation, and agreed with Murphy that the graft was eventually absorbed. Bone growth was mainly subperiosteal and the graft atrophied. He agreed that transplanted bone could grow and the truth of Wolff's law of reaction to stress and strain was unquestionable. But a sense of proportion had to be observed in applying this law to grafts. It was well recognised that immobilisation of a part in plaster caused disuse-atrophy in the bones of that part. It was therefore absurd in graft cases, which are always immobilised, to expect the graft to grow while the recipient bones were atrophying. The good results obtained by Albee were admitted, but his conclusions were not acceptable. The speaker did not use intramedullary grafts as they caused pressure-atrophy of the recipient, and also blocked the medulla. Sclerosed bone was usually considered as quite unsuited to taking a graft, but in his opinion it received grafts very well. As was well understood there were two simultaneous processes going on, osteoblastic and osteoclastic; if the former was in excess, the new shaft was completed before the grafted was absorbed, but if the latter, then the graft was absorbed before new bone had appeared in any quantity.

In remarking upon Albee's contention that some spinal grafts of compact bone had become cancellous, Mr. Mamourian pointed out that there had been no such metamorphosis, but that the cancellous bone originated from the spine. He contended that grafts simply stimulated the osteogenetic cells of the recipient bone and periosteum to new growth. He went further in pointing out how much new bone formation there was in cases of chronic bone infections, and he contended that slight infection is a stimulus also to bone growth. This led him to present a new aspect of bone-graft surgery—viz., that it was not necessary to wait for all sepsis to subside before operating, but rather would he lay down this important fact—viz., that an infection of low virulence was of assistance to the success of bone-grafting, the truth of which he had proved in many cases.

In concluding, Mr. Mamourian showed a collection of most interesting X ray photographs, illustrating the points of his paper.

FRIDAY, JULY 22ND.

The third session, Mr. ARTHUR COOKE (Cambridge) being in the chair, was devoted to a discussion on the

Diagnosis and Treatment of Injuries of the Intestines.

Mr. G. GORDON TAYLOR (London) in his opening address alluded to two classes of injured intestines—namely, those caused by a severe, or even by a slight contusion of the abdominal wall, and those associated with perforating wounds. It was the former which presented such difficulties of diagnosis. He quoted the series of 132 cases recorded in 1908 by James Berry and Paul Giuseppi, and Zachary Cope's series of 44 additional cases up to 1912. The symptoms laid down at that time were: abdominal pain, local tenderness, rigidity, vomiting, rising pulse, marked shock, bruising of abdominal wall, diminution or loss of liver dullness. He maintained that "the prognosis is so intimately related to early diagnosis and to early operation that the case should be kept under observation, and the pulse counted every half hour; and I would submit that, whenever there exists the slightest suspicion of intestinal injury, the abdomen should be explored forthwith." He went on to say that retroperitoneal injury to the duodenum was sufficiently common to demand investigation in all cases. The toilet of the peritoneum varied with the amount of soiling, which, if limited, should be mopped up, and the abdomen closed without drainage. In cases of wide contamination the peritoneum must be drained, usually by a tube in the pelvis.

When dealing with perforating wounds of the abdomen the diagnosis was not nearly so difficult, nor was the line of treatment at all doubtful, for the results of expectant treatment were appalling, and the war results of early operation were encouraging. Signs and symptoms were often self-evident—e.g., the passage of fæces and flatus through the wound, persistent bleeding, or protrusion of omentum, or other abdominal contents; and again hæmatemesis, passage of blood per rectum, and very marked shock.

has realised by operative experience that the primary focus is the acute appendicitis, the acute cholecystitis or ruptured ulcer, &c., and has impressed upon the general practitioner the importance of early treatment. Secondly, the pathologist has clearly shown that the adhesions are defensive in nature, and that to break them down and irrigate the whole cavity is not only of no value, but of great danger. Lastly, a cytological examination has been of great assistance both in diagnosis and prognosis; for in his opinion the only true guide to a knowledge of the patient's reaction to the infection is the number of the large mononuclear leucocytes.

B.—*The knee-joint.*—In the same way the treatment of joint infections went through the following phases during the war: (1) the use of powerful antiseptics, which led to amputation; (2) the use of saline dressings on an open joint, which had the same ending; (3) drainage-tubes, which inevitably led to disaster; (4) excision of damaged tissues; (5) lastly, opening, evacuating, and immediate closing of the joint.

Mr. Wade, bearing in mind the close analogy between the peritoneum and the knee and the pleura, has modelled his treatment of acute pleural empyema on the same lines. He recommended that the pleura should be freely opened, all pus evacuated, care being taken that all loculations were broken down, and then the wound closed as early as possible. The opening in the pleura was a matter of some controversy as physiologists condemned the wide openings as practised during the war. Personally he made an opening just large enough to permit of a thorough examination of the cavity, and so planned that it would fall together when the tube was removed. He used a short tube and led away the discharge into a receptacle containing a disinfectant, but he took out his tube as early as possible, usually at the end of 48 hours. He realised that some cases could be aspirated satisfactorily, but the value of aspiration needed thoroughly reviewing. He also thought that the value of disinfection of the cavity should be fully tested. But he was convinced that the method he had suggested was the most satisfactory. The technique was exactly as laid down by Prof. Rutherford Morison during the war and could be summed up as (1) opening; (2) drainage; (3) early closure.

Discussion.

Colonel A. FULLERTON (Belfast) said that he and his colleagues in France would have agreed most heartily with Mr. Wade. He laid stress on the danger of drainage-tubes which, while allowing the escape of septic material, invariably introduced other organisms. It was due to this that so many knee cases were lost in the early part of the war. In gunshot wounds of the chest, he opened the pleural cavity, removed the foreign body, and closed the chest. If infection followed, he gave a fair trial to aspiration, which in many cases was successful; but if it failed then the chest had to be opened, disinfected with bipp or flavine, and then drained, but he dispensed with the tube as early as possible.

Mr. T. P. DUNHILL (London) raised three small points: 1. The possibility of immediate suture was always to be borne in mind. He evacuated the contents of the cavity not by swabbing, but by means of a Sprengel's suction pump, which he considered much more efficient. His cases in France usually healed after removal of the foreign body and primary suture, but he pointed out that, when aspiration was necessary, it should be done every day. 2. Some cases in hospital practice were of a doubtful diagnosis, in which pus was suspected, but not found with a needle. Here he strongly recommended an exploration of the pleural cavity just as one did an exploratory laparotomy. The chest should be carefully explored, and it was surprising how often pus was found in quite unexpected places—e.g., around the apex of the lung instead of at the base as had been diagnosed. 3. He considered that the most valuable anæsthetic was intratracheal ether, except in the most acute cases.

Mr. PURVIS said that his experience of wounds of the knee-joint in the East, which had been treated by the Rutherford Morison technique, was so uniformly good that he felt convinced that the application of the same principles to the chest could only have the most brilliant results.

Mr. G. H. EDINGTON (Glasgow) remarked that he would have been glad to have had more data concerning the infecting organism, because in his opinion the course of the case varied with the nature of the infection, those due to the pneumococcus clearing up the most rapidly. Again, those cases in which thick pus and fibrinous masses were present were of much better prognosis than those having thin watery fluid. He never had used antiseptics, but always drained; and in his opinion drainage-tubes were not the bogey that they are made out. He retained his tubes for 14 days, cut them flush with the skin, and strongly deprecated the use of tubing draining into a bottle. He did not agree to the analogy between the pleura and the peritoneum, for in the latter the contents were adaptable to the local condition, but in the chest only the lung was adaptable.

Mr. JAMES BERRY (London) raised two points of practical importance: 1. The technique in dealing with very ill patients with large collections. He had seen cases die because of movement during the anæsthetic. The patient was so placed that the affected side projected over the side of the table, and he operated from below. 2. After-treatment. He always covered over the whole wound with oiled silk, which acted in a valvular manner, and allowed discharges to be expelled during inspiration, but sealed the wound in expiration.

Mr. F. C. PYBUS (Newcastle) had been impressed by the high mortality in children, and advised the following steps in the treatment—viz., early diagnosis, large incisions with flavine irrigations, very careful examination of chest each day, much earlier treatment to expand the lung. For this condition he urged getting the children up sooner and letting them run about. He mentioned a recent communication from America, in which puncture and Carrel-Dakin irrigation had reduced the mortality to 2 per cent. He maintained that thoracotomy was much more dangerous than a laparotomy.

Mr. A. LUCAS (Birmingham) thought that treatment and prognosis largely depended upon the infecting organisms. He advised aspiration when possible, otherwise incision, but he objected to tubes. He used a local anæsthesia, and got his patient up early.

Mr. C. P. CHILDE (Southsea) mentioned a case in which the condition persisted because of a tube which had fallen into the chest.

Mr. H. S. SOUTTAR (London) insisted that attention to small details was of greatest importance. In reality these cases were favourable for treatment and he advised: (1) Patient to be placed in position before starting and not moved afterwards; (2) regional anæsthesia; (3) patient to be on the face almost in the supine position; (4) incision not far back, but its centre to be in the mid-axillary line; (5) drainage quite unnecessary; (6) incision will close, being a valvular one.

Prof. MORISON congratulated Mr. Wade on his paper, and was delighted at the comparison drawn between the peritoneum, pleura, and joints. It was one which he frequently made, but had not heard any speaker take such a line before.

Sir WILLIAM MACEWEN, Mr. A. M. MARTIN, Mr. W. J. HADLEY, Mr. MCADAM ECCLES, Mr. C. F. CUTHBERT, Colonel CONNOR, Mr. W. S. DICKIE, and Mr. A. COOKE also contributed to the discussion.

Mr. WADE, in reply, said that Mr. Berry and Mr. Souttar had taught him a great deal. He did not agree that the outlook of a case depended upon the nature of the infecting organism. The feature of the greatest import was the nature of the reaction of the soil to the seed. If a blood film showed that the organisms were being infested by the polymorphonuclear leucocytes and they in their turn were being destroyed by an excess of large mononuclear leucocytes, then that every injury to the abdomen must be treated as if it were a penetrating wound.

Mr. F. J. S. **HEANEY** (Liverpool) was greatly struck by Prof. Morison's remarks, and quoted a case of his own where a slight kick in the abdomen had resulted in a great rent in the jejunum. He remarked that obstruction from adhesions not infrequently followed.

Mr. D. **WILKIE** (Edinburgh) emphasised the attitude of the surgeon, who should always open the abdomen whenever any doubt existed.

Mr. E. F. **FINCH** (Sheffield) commented on a class of case not previously mentioned—viz., perforation of the intestine by foreign bodies within it. He quoted two cases of such injury by fish bones in the transverse colon.

Mr. **SOUTTAR** said that before operation was undertaken four conditions must be present—viz., first-class assistance, theatre arrangements, anæsthetist, and proper control afterwards. He mentioned cases in which fæcal fistulæ followed operation, and advised that short circuit held the only hope of cure.

Mr. **CHILDE** asked for information upon the greatest length of small intestine that could be removed compatible with the life of the patient afterwards.

Mr. **TAYLOR**, in reply, said that he believed the longest recorded resection was 18 feet, but his longest resection for contusions was 6 feet 6 inches. The lesson to be learnt was that all injuries should be immediately sent to hospital.

Mr. **CHILDE** demonstrated a method of resection of the stomach and intestines by means of heavy crushing clamps and the Paquelin cautery.

Demonstrations.

Mr. G. **GREY TURNER** (Newcastle) showed:—

(*a*) *Cleft Palates* (20 cases).—These cases were all well healed, and Mr. Turner demonstrated that some of them spoke quite well, others indifferently. One girl especially, who was operated upon quite late, spoke exceedingly well, and it was obvious that the functional result depended largely upon the intellectual standard of the patient.

(*b*) *Implantation of Ureters* (6 cases).—A full table of results is appended. It will be seen that the cases were those of complete ectopia or of epispadias with incontinence of urine. His operations were always done in two stages—first the left ureter, then the right. He considered that by leaving one ureter the patient is able to combat any pyelonephritis that may arise in the kidney of which the ureter has been transplanted. The infection having subsided and immunity established, the other ureter is transplanted. He divides the ureter about 1 to 2 inches from the bladder, and puts on the proximal end a Crile's clamp to avoid leakage. The distal end is ligatured, carbolised, and dropped back. The left ureter is implanted into the sigmoid flexure by a method similar to Witzel's gastrostomy. The right is inserted into the neighbourhood of the recto-sigmoid junction. His results are most striking when one considers that out of 8 cases 5 have complete continence, and 1 is incontinent at night only.

(*c*) *Liver Tumour.*—Mr. Turner then showed a boy who was admitted last February with a tumour in the upper part of the right abdomen. It was found to be a tumour in the right lobe of the liver and Mr. Turner proceeded to remove it. A wedge-shaped resection was done, including the gall-bladder, All that was left was the left lobe, the structures of the portal fissure, and the vena cava. The only bleeding of importance was from branches of the hepatic artery, and these were clamped as cut. The tumour proved to be a rare one, resembling a pure adenoma, but containing no ducts, and has been called a hepatoma. The boy, five months afterwards, appeared in the best of health.

Prof. **MORISON** demonstrated on cases of septic wounds, amongst them one of tuberculous disease in and around the tendon sheaths of the wrist. These had been treated with bipp and had healed well. He showed a series of cases of bone cavities treated as he has laid down and then filled with fat grafts. It was interesting to find fat grafts succeeding so admirably. Another series of cases was shown illustrating bone-grafting.

Cases of Intraperitoneal Implantation of Ureter into Pelvic Colon.

No.	Init.	Sex.	Before operation.		Date of opern.	Stages and time between.	Complication.	Result.	Period since opern.	Present condition.	Remarks.

SECTION OF NEUROLOGY AND PSYCHIATRY.

WEDNESDAY, JULY 20TH.

At a meeting of this section, Prof. **ASHLEY MACKINTOSH** being in the chair, a paper on the

Diagnosis and Treatment of Borderland Cases

was read by Prof. G. M. **ROBERTSON** (Morningside Mental Hospital). Discussing the nature of the borderland, Prof. Robertson stated that on one side of the boundary was the region of the neuroses consisting of disorders presenting such symptoms as spasm, paralysis and sensory disturbances; while on the other side was the territory of the psychoses, which included such disorders as mania, melancholia, and dementia præcox. Between these no hard-and-fast boundary existed. The neuroses and psychoses cavity, and to do so took two X rays, one before and one after the injection of bipp under pressure. He showed lantern slides to demonstrate how far the lesions in the soft parts might extend, and he insisted that the removal of the whole septic tract was essential to the success of the operation. The steps in his operative procedure included: (1) excision of the sinus and tracts in soft tissues; (2) free subperiosteal exposure; (3) location of the bone cavity and converting it into a groove; (4) treatment of this bony groove with spirit and bipp; (5) soft tissues allowed to fall in and wound sutured up.

Discussion.

Mr. A. H. TUBBY (London) said that his war experience was confined to base hospitals, and he must admit to having had considerable difficulties with these fractures. Taken all round, the Thomas knee-splint was not favourable for all cases, the great drawback being that so much education in its application was needed before it was properly handled. They had favoured the Hey Groves technique, and had very good results. He had been much struck by the amount of traction necessary for the lower limb, and how well the limb stood it. Ten pounds had been used at the beginning and later 30–40 lb. Sinclair's glue was the best adhesive, and calipers were most useful in difficult cases. He had started using calipers with the gravest apprehension, but had been converted.

Mr. HAMILTON RUSSELL (Melbourne) remarked that the aspects of the case were so many, and that he would later deal with the mechanics of extension; therefore he would confine his remarks to the soft tissues. He agreed with Mr. Tubby's remarks on the Thomas splint, except that it was invaluable for transport. But did not share his liking for Hey Groves's work, and would particularly condemn calipers; and further he considered such heavy weights as quite unnecessary. He felt that we needed great discrimination in dealing with war experience and its lessons, especially with regard to adopting them into civil practice. The point of most vital importance was to avoid further damage to the tissues or weakening the natural resistance of the patient. For these reasons he deprecated the use of strong antiseptics.

Mr. MAX PAGE (London) would insist on the adoption of the new nomenclature—viz., "open fractures," not "compound fractures." He recognised three distinct cases of open fracture: (1) direct, in which the skin, muscle, and bone are all damaged at the site of injury; (2) indirect, in which the sharp fragments pierce the skin; (3) secondary, where skin sloughs over a fracture. He maintained that contamination and treatment varied widely in each. In the direct variety the infection was marked and liable to become a fulminating one, and in these cases it was necessary to excise the whole wound tract, including the infected bone ends. This was not always practicable because of shortening and the presence of main vessels and nerves in the wound. In the indirect variety the infection was superficial and the deep structures could only be infected by reposition of the bones. These cases should be fixed on a splint exactly as they were, until operation could be undertaken. Then the skin should be thoroughly cleansed, the protruding bone cleanly sawn off, fracture reduced, wound excised, and wound sewn up. He also added that primary amputation must always be considered in all direct fractures, and that internal splinting in these cases was undesirable. Tourniquets were condemned. He advocated much earlier physio-therapy than Mr. Dunn. Calipers and transfixion called for great care, and he considered that bad fractures of the tibia were most suitably dealt with in a plaster case with convenient interruptions.

Mr. WADE said that they were attempting to establish a routine for all these fractures—viz., immediate fixation in a Thomas splint without a tourniquet. The administration of anti-tetanic serum depended entirely upon the district the accident occurred in. He regarded splints as an occasional unfortunate necessity preferring support of the limb on pillows with a direct weight extension, with counter extension by the body weight. Massage and movement were of the utmost importance.

Mr. EDINGTON operated in every case, cleaned up the limb, irrigated the wound with carbolic lotion, and did not excise the wound. He used a half-box wooden splint for the tibial fractures. If results were not satisfactory in a week he never hesitated to use a plate, which he removed after four weeks. He disliked transfixion pins.

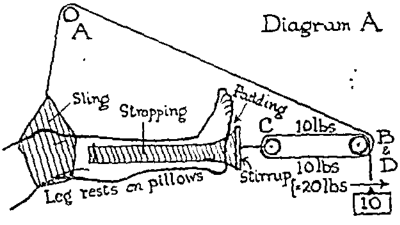
Colonel FULLERTON had seen so much of Major Sinclair's work that he was entirely convinced of its efficacy. He had difficulty with both glue and adhesive plaster, and had never hesitated to use calipers or pins, and as he had not seen injury to result from extension through the ligaments of the knee-joint, he put his calipers into the head of the tibia. Patients who had had glue and plaster and calipers unanimously preferred the last. He thought excision of wounds had come to stay, but he did not use antiseptics.

Prof. MORISON insisted on every case being opened up, and in support quoted a case of his own. A sergeant was admitted with a clean in-and-out bullet wound of the thigh with a fractured femur. The wounds were scabbed over, the temperature was normal, and the man felt fit. For ten days this continued, and on the eleventh he had a rigor and nearly died from acute osteitis of the femur.

Mr. RUSSELL then read his paper on the closely allied subject of

Theory and Method in Extension of the Thigh.

The speaker said that his interest in this subject was brought about years ago by seeing the son of a great friend, who had had a fractured femur, well treated by a practitioner. In spite of this the boy, after ten weeks, had non-union and 3½ inches of shortening. Why was there this shortening? He explained that shortening of the limb in fractures of the femur was due to the tone of the long muscles going from the pelvis to the upper end of the tibia. This tone or "physiological stretch," was maintained by the femur, and when once it was broken shortening occurred and, moreover, became progressive as time went on. Our aim, therefore, should be to pull out these muscles to their normal length. This was quite easy but for two factors: (1) active muscular contraction, due to fear, pain, &c; (2) weight of the limb and gravity. He had therefore devised a method of extension which, in his opinion, gave perfect results. It avoided splints and was most convenient for nursing purposes, and was absolutely comfortable for the patient.



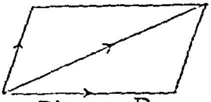


Diagram B

The procedure was as follows: A wide sling is placed around the knee, and a strapping extension placed on the leg (*not the thigh*) ending in a stirrup, the cord of which is attached to pulley C (see diagram A) A cord attached to the knee-sling passes to a Balkan

The close supervision sometimes deemed necessary for patients in whom suicidal tendencies might be suspected might be definitely hurtful and delay recovery. The choice lay between taking risks and a harmful measure of supervision, and risks sometimes had to be taken in the patient's best interests. The recognition of early cases was often difficult and early means of diagnosis was badly needed.

Dr. A. E. Carver (Birmingham) did not deal specifically with borderland cases. He believed that in the case of neuroses in pensioners the financial element retarded recovery, and was unfavourable to treatment. He thought that prolonged separation in an institution from the patient's home surroundings was undesirable and that as early as possible a return to work was essential. Cases of the kind described by Dr. Ivy McKenzie could not be classified, as they were all too complex in origin.

Dr. W. L. Ruxton (Newcastle) dealt with the difficulties of the general practitioner in dealing with early mental cases. The indications for certification constituted one of these. He thought that in early melancholics the presence of hallucinations of hearing was an imperative indication for control in a mental hospital. Often the machinery of certification, even the emergency certificate, was too cumbrous and slow, and the practitioner was not seldom compelled to send his patient to the workhouse infirmary to avoid the risks of delay.

Dr. Mary Sturge (Birmingham) expressed the view that physical factors were very important, and were apt to be overlooked in dealing with such cases. She quoted cases of depressed and discontented women who had been relieved and altered in disposition by the adoption of such simple measures as the use of a kidney belt, a pessary, or a vaccine.

Dr. J. Middlemass (Ryhope) pleaded for a modification of the existing law in respect of mental hospital treatment. For patients of the poorer classes voluntary treatment apart from certification was urgently required.

Dr. Mackie White said that legislation in the State of South Africa was far more enlightened than our own. There, a patient could voluntarily seek treatment in a mental hospital, and during the necessary period of stay in hospital could be maintained at the public expense.

Dr. W. R. Dawson (Dublin) said that in considering a borderland case, every aspect of the patient's life must be taken into account. Psychiatrists had long realised this, and it was now being discovered anew by non-psychiatrists. He agreed with Prof. Robertson that the dangers of suicide were greatest at the later stage of convalescence.

Dr. W. H. Bryce believed that an open mind was essential in dealing with early mental cases from the point of view of treatment. There was too little fusion of ideas, and treatment was carried out by disciples of different schools of thought along narrow lines. Physical and psychical symptoms might co-exist, and both had to be taken into account, while their relationship was often difficult to determine.

Prof. Ashley Mackintosh (Aberdeen), in concluding the discussion, said that errors of diagnosis in respect of borderland cases were too frequently made by neurologists, and many obvious melancholics were treated as simple neuroses with unhappy results.

Prof. Robertson, in reply to the discussion, defined melancholia as a periodic functional psychosis, and emphasised again its dangerous character. In such cases suicide was not impulsive, but it was long premeditated. The patient's friends should always be told of the possible dangers, and thus be made to share in the responsibility of deciding for or against supervision in a mental hospital.

Thursday, July 21st.

Dr. Harry Campbell (London) read a paper on

The Nervous Diathesis and the Blood.

The growth, structure, and functioning of the neurone depended upon its heredity and its environment. The environmental factors were plasmic and non-plasmic. The blood and the perineuronal lymph constituted the plasmic environment, the non-plasmic being synaptic and inter-neuronal. The state of the plasmic environment was responsible for whatever disease might occur to the neurone, the progressive deterioration of which during adult life depended entirely upon changes in the plasmic medium. Senility was thrust upon the nervous system by the plasma, and if this were to remain adolescent in its qualities senility could not occur. Plasmic defects might be inborn or acquired. Functional and organic nervous diseases were due more to inborn plasmic defects than to primary neuronal defects. Substances having a drug-like action were carried in the plasma and bathed the nerve cell. Two great groups of substances were present, nerve stimulants and nerve depressants. He thought that a congenital craving for alcohol depended upon the lack of these nerve stimulants, which the organism sought to make up from outside. The feelings and the emotional temperament were all determined by the blood. The endocrine organs all poured their secretions into the blood and thus influenced the nervous system. The various symptoms associated with abnormal blood states were briefly described.

Dr. George Riddoch (London) spoke of

Some Points in the Management and Treatment of Paraplegia.

The management of paraplegics consisted principally in the care of the bladder, rectum, and skin. The usual cause of death in such cases was urinary sepsis with toxæmia. After an acute spinal lesion, the bladder passed through an initial stage of paralysis with retention of urine, and then under favourable conditions, entered upon a phase of automatic activity. During the stage of retention, it was important to avoid both infection and distension of the bladder. With this in view the method of manual expression had been recommended, but it was not free from danger and did not completely empty the bladder. The safest and most effective method was to tie in a catheter, which need be changed only every three days. In this way repeated introduction of the catheter was avoided and the bladder was never allowed to distend. An essential preliminary to each introduction of a catheter was the washing out of the urethra, in order that organisms in its walls might not be pushed up into the bladder. Irrigation twice in the 24 hours with normal saline solution was recommended. In all such procedures the strictest aseptic precautions were necessary. When the bladder began to evacuate itself, it should be encouraged to do so, and when on irrigation signs of back-flow were seen, the bladder should be allowed to discharge its contents. The urine should be kept acid, and for this purpose acid sodium phosphate was used. If cystitis supervened, it might be necessary to perform suprapubic cystotomy. The rectum passed through the same two stages as the bladder. In the first, distension should be avoided by the use of paraffin, aperients, and enemata. The skin, while sound, should have a daily washing and friction with soap and water. The excessive sweating which often rendered its care difficult in cases of total transection, could be minimised by careful attention to bladder and rectum, distension of which was a fruitful cause of hyperidrosis. In the general management of cases, fresh air and the use of wheel chairs, as soon as the local surgical condition of the spine allowed, were important.

The Physiology of Symptom Production.

Dr. F. M. R. Walshe (London) read a paper on the Physiology of Symptom Production in Disease and Injury of the Nervous System. In spite of many notable recent advances in neurology, very little was known of the physiological processes underlying the manifestations of disordered function in the nervous system. As neurologists they had somewhat rigid views as to the principles underlying the dissolution of function in nervous disease. The hypotheses dominating neurological thought had ceased to be favourable to progress in some respects and were

He emphasised the danger of being misled by the site of origin of the wound, for he had known cases in which the wound was in the thorax, supraclavicular fossa, even the thigh, and yet the most serious lesion was intestinal. In this respect buttock wounds were very dangerous. Doubtful cases must be approached on the same lines as non-perforating injuries. He insisted that "In the abdomen there are no insignificant wounds. Every wound, whether penetrating or not, should be thoroughly explored, excised, and disinfected. In these days of improved resuscitation and operative technique the patient will suffer no detriment; nay, rather, with the excision of his parietal wound, his convalescence will be more sure, his wound will heal more kindly, and the surgeon will have that comfort which comes of assurance that no intraperitoneal injury has been overlooked."

Treatment of Injured Intestine.

Mr. TAYLOR brought forward an overwhelming array of war statistics to prove that suture was infinitely preferable to resection; at the same time it was necessary to look sanely on the subject, for it was obviously useless to cobble a crushed and lifeless piece of bowel, or one which had been widely detached from its mesentery. This specially held true for large intestine, where suture nearly always sufficed, but where resection was necessary occasionally for infarcted gut, &c. In dealing with the large intestine the surgeon must remember how frequently wounds were of a perforating type, and must be quite sure that no retroperitoneal infection of the cellular tissues had taken place. These were very sinister cases, for these tissues responded badly to infection, they were difficult of access, and the gut held sutures badly. Colostomy or cæcostomy, if done early enough, was of great assistance in these cases. He mentioned one other type of case, in which there is gangrene of the mucous membrane, with laceration of the muscle coat; and here nothing sufficed but a resection.

He then proceeded to deal with multiple resections. Previous to the war, if the gut were badly damaged in two places, the whole area of gut was resected, thereby sacrificing the intervening healthy portion; or one area was resected and the other cobbled up as well as might be. The war results, too, did not favour multiple resections; but in civil practice, double, treble, quadruple, and even quintuple resections were recorded. In his opinion the fatality of multiple resections was due not to the operative shock, but to the severity of the injury. He drew attention to the extreme fatality of duodenal injuries, and particularly wounds of small intestine combined with a lesion of the pancreas. Wounds of the jejunum were of better prognosis than those of the ileum. Wounds of the urinary bladder associated with intestinal injuries were also of bad prognosis.

In conclusion he asked that the lessons of those resuscitation wards of the casualty clearing stations should not be forgotten. Anoci-association and blood transfusion were invaluable methods of saving life, and had revolutionised the standards by which the operability of a patient was judged. It had been laid down that operations on patients with a pulse-rate of 120 were of very bad prognosis, and later on that no patient of a pulse-rate of 140 should be touched. But blood transfusion recalled many a man to a stage when operation afforded the means of saving his life.

Discussion.

Mr. BERRY said that he would confine himself to traumatic ruptures without external wounds. Much had been written on the three alleged causes of these injuries—viz., the crush, tear, and burst; the crush was far the most common, the burst being a pathological curiosity. The table shown was of interest.

He considered that diagnosis could and should be made earlier. The history was important, and one symptom was extremely important—viz., a point of intense continuous pain—and when this was combined with local tenderness and rigidity an immediate laparotomy should be done. The shock was not due to the perforation per se, but to some associated injury—e.g., to cœliac plexus, or the flooding of the peritoneum with intestinal contents. The reason for the absence of peritoneal flooding in so many cases was that the intestine became spasmodically contracted just above the perforation. This was impressed upon him in the case of a Russian soldier who had sustained an injury 14 hours previous to operation. On exploration no soiling of the peritoneum was found, and the gut was contracted above, but handling during the examination caused relaxation, and a great gush of fæcal contents. He considered absence of liver dullness a sign of fatal prognosis.

	Ten London hospitals.		The Zeidler clinic.	
	1893–1907.	1908–1912.	1897–1910	Total.
Numbers	132	41	52	
Operations	81	30	40	
Operative recovery	17	9	8	
Duodenum	23	5	1	29
Jejunum and ileum	92	37	48	177
Colon	10	2	3	15
				231

Clinically he recognised three types of case: (1) Rupture of all coats at the time of injury; (2) secondary rupture, where the peritoneum was intact and the patient would walk into hospital; (3) rupture of gut and other injuries. In treatment he advocated a sufficiently long incision to enable a thorough examination of the abdominal contents, repair by simple suture, local sponging of peritoneum if necessary, and drainage if much soiling. He considered the after-treatment most important. He propped his patients up and gave nothing by the mouth for four days, along with continuous drop-saline per rectum.

Mr. V. Z. COPE (London) associated himself with Mr. Gordon Taylor's dictum that all wounds of the abdominal wall must be treated with the gravest suspicion. He laid down that probing of a wound in the parietal wall should almost constitute malpraxis. He recommended a laparotomy of every case, combined with excision of the wound. In cases with contusions of the abdominal wall he considered that there were only two signs of real assistance (hæmorrhage and spinal and thoracic injuries excluded): (1) pain, (2) alteration in pulse. The pain is of a fourfold nature—viz., that complained of by the patient, that seen in the face, that elicited on pressure on abdomen, and that elicited by rectal examination. He did not agree with Mr. Berry's pessimism over absence of liver dullness, and quoted a case of Mr. C. A. Pannett that survived operation 30 hours after rupture. Vomiting, too, may be a guide to peritoneal injury. He drew attention to primary meteorism as a complication to be guarded against. He considered that results had shown marked improvement; of the last five cases at St. Mary's Hospital all had recovered.

Mr. HAMILTON BARCLAY (Newcastle) confined his remarks to gunshot wounds. He advised a mid-line or paramedian incision, with systematic search of the whole abdominal cavity. He quoted a case of a bullet wound, in which the wound of entry was over the right hip-joint. There were two wounds of the cæcum, four holes in the first inch of the jejunum, and the bullet was in the spleen. Hæmorrhage should always be dealt with first, and evisceration was to be avoided as far as possible.

Prof. MORISON considered that one very essential factor had been missed—viz., the education of the general practitioner. He quoted cases of trivial injuries accompanied by transient shock with a stage of apparent complete recovery followed later by collapse. He insisted that the sequence of events was as follows: (1) There was always shock at the time, however slight and transient; (2) a reaction stage always followed; (3) stage of peritonitis or hæmorrhage. He laid down that it must be a general rule

Reviews and Notices of Books.

Mental Hospital Manual.

By John Macarthur, M.R.C.S., L.R.C.P., Senior Assistant Medical Officer, London County Mental Hospital, Colney Hatch. London: Oxford Medical Publications. 1921. Pp. 215. 15s.

In his preface Dr. Macarthur says that his book is an endeavour to place before a newly joined medical officer in a mental hospital those methods of treating the insane which experience has proved to be satisfactory. This purpose is successfully accomplished, provided it be remembered that the hospital is a large public institution in which careful organisation and elaborate routine are absolutely necessary. In an institution with some 2500 patients of all kinds, with authority centralised in a single medical superintendent, measures must be taken to safeguard the patients, prevent accidents, and fix responsibility should anything go wrong that would be unnecessary in a small hospital. The book contains, printed in full, the wording of no less than 20 notices and charts, and all these in addition to the multifarious statutory notices required by Act of Parliament and the Board of Control. Among these are forms dealing with diet, medicine, seclusion, weights, struggles, sleep, suicide, escapes, fits, visitors, tuberculosis, dysentery—by which it is seen that much reliance is placed on written instruction and reports. But before sympathising with the young medical officer inclined to rebel against so much routine, the nature of the work and the size of the institution must not be forgotten.

The first paragraph of the book quotes the late Dr. Charles Mercier as saying that a mental hospital exists "for the detention under care and treatment of persons who are inclined to be melancholy or turbulent, have tendencies to injure themselves or others, and are unable to protect themselves from ordinary sources of danger." Dr. Mercier used the word "asylum," and his definition is sound, but when Dr. Macarthur misquotes him by using the term "mental hospital" he fails to notice an important distinction which affects the whole point of view. The central thought of the one is protection and detention, and of the other treatment. This is no pedantic refinement, for evidently Dr. Macarthur means asylum throughout and not hospital. Nowhere in his book does he mention voluntary patients. It is never imagined that persons disturbed in mind should themselves apply for treatment and remain of their own free will. It is of course true that the law is so interpreted that voluntary patients cannot be received into our county and borough institutions, but a medical man writing such a manual as this should have a wide outlook, and not accept the existing procedure as satisfactory. Would there not be less prejudice against these most efficient institutions if there were a constant stream of voluntary patients passing through them? They could then rightly be called hospitals. The critical reader cannot but wish that there was less asylum and more hospital throughout the book. The impression is given that the new patient is engulfed in an inexorable machine, magnificently designed, perfect in its organisation, but lacking in soul and sentiment. Speaking of the admission of new cases, we are told, "in the case of a female the patient is stripped, weighed, measured, and put to bed in the presence of the head nurse, the charge nurse of the ward, and the relieving officer's female officer, in order that all marks, bruises, etc. . . . may also be seen by the representative of the guardians." This is not a hospital method of receiving a new patient, and cannot be helpful in treatment. One wonders what a sensitive depressed patient would think of her reception, and whether many do not resent this routine as a needless indignity. Again, the printed rules say that a patient cannot be visited until a month has elapsed after admission. Surely this may sometimes be a real hardship, whilst fixed rules of this kind create much prejudice against asylums. In two places the author recommends the "thorough and sudden searching" of all the patients in the ward on account of the tendency to collect rubbish and contraband articles. Whilst realising this may be necessary sometimes in certain wards, an impression is given of an arbitrary interference with personal freedom that seems unnecessary. Indeed, it almost seems that the guiding principle throughout the book is "safety first." Because once an ingenious and misguided patient made a screw-driver out of a stay-busk, surely the peace of mind of generations of patients should not be disturbed in order to prevent a repetition. Safety first is a comfortable formula for officers and staff, but is often positively hurtful to patients. How often it happens that convalescence begins when patients are trusted. There is good reason to believe that maniacal states may continue indefinitely under irritating surroundings, and similarly depressed states continue until rigid supervision is relaxed.

These criticisms are directed perhaps more against the existing system of great county asylums than against the subject matter of this book. If Dr. Macarthur had not strictly limited himself he could no doubt have said much on the wider subject. It would have been interesting to hear what he thinks of centralised management, which places all authority in the hands of one person, and more, what of the system by which several of these asylums are grouped together, with the result that liberty of action is curtailed by standardised routine. There is, moreover, no reference to research or the coördinated study of mental disease, nor is the subject of study leave mentioned. The importance of the diploma of psychological medicine and its indirect value in arousing interest in the scientific aspect of the asylum officer's work is ignored.

The administrative duties are excellently dealt with, and the volume is full of sound practical advice. Straightforward dealing with the insane is advocated whole-heartily—e.g., any attempt to give drugs by subterfuge or in food is condemned—medicines should only be given openly, and if refused in serious cases, instead of deception, the stomach tube should be used. He urges the value of good food, and suggests that it is both wiser and more economical to spend money on suitable diet than on drugs. As a practical guide to the treatment of the insane the book is valuable, and we advise all who undertake the treatment of mental cases in private to read it, so that they may learn the high standard of treatment that is given in our public hospitals. But in dealing with excitement and sleeplessness too much reliance seems to be placed on drugs. Nearly all newly admitted patients have been already overdosed with sedatives, and yet the use of paraldehyde and hyoscine is discussed on the day of admission "if it be necessary to quieten the patient." When advocating the use of 2 minims of croton oil in half an ounce of castor oil in acute mania with constipation, the author adds, "it need hardly be pointed out that this drug (croton oil) should be used as medicine, and no idea of punitive treatment should ever be suggested with regard to its use." And in speaking of cold baths a similar remark is made. It should be unnecessary to say these things, but the painful impression is given in another column that such episodes have happened.

It is to be hoped that Dr. Macarthur will soon be asked to prepare a new and revised edition, for the book is a valuable contribution to medical literature.

Experiences of an Asylum Doctor.

With suggestions for Asylum and Lunacy Law Reform. By Montagu Lomax, M.R.C.S. London: George Allen and Unwin. 1921. Pp. 256. 12s. 6d.

Dr. Lomax's book is dedicated to the insane poor in sympathy with their sufferings and in the hope of alleviating their hardships. Since it is an attack both passed gradually from one to the other, though not all neuroses developed into psychoses. Further, this borderland was not a negligible strip of territory but a broad and extensive domain, which from its influence upon human life was a most important one. By the term borderland cases was meant those in which some form of disorder of the mind played an important if not an essential part. In some of these the symptoms themselves were clearly mental; such symptoms were phobias, anxiety states, and compulsive obsessions. Serious cases presenting mental symptoms amounting to legal insanity were excluded from the group, being definitely across the border. Even those cases which presented symptoms of an apparently purely physical character, when studied more carefully from within, were often found to be mental in origin and capable of cure by purely mental agencies. Therefore the borderland group included all cases presenting symptoms of a mental order, except those of certifiable insanity. It might be desirable to limit this large group by the exclusion of cases in which the symptoms were slight and evanescent. Three considerations arose from these conclusions. All symptoms of ill-health apart from those arising from structural alterations in the tissues might be considered as mental in origin. Pain was a purely mental symptom, and even when due to organic disease might be removed by purely mental means. Further, organic changes might depend primarily upon mental or emotional factors. Therefore all symptoms must be looked at from a mental point of view. Secondly, the value of psychotherapy had been found to be almost unlimited. This most primitive form of treatment had always been successful when applied with discrimination; it was the only form mentioned in the Bible, and was instinctively administered by every mother to her child. The psychiatrist had systematically practised it for over a century. Pinel, Tuke, Conolly, and Clouston had all employed it in their work, though they had never systematised their methods, designated them by any particular name, nor had they bound themselves by any single method of approach. Their psycho-therapy was mental healing pure and simple, was followed by excellent results and was not based upon abstract speculations. Finally, the number of nervous cases now regarded as functional had enormously increased. The neurologist had formerly been inclined to reproach the psychiatrist because the latter was unable to demonstrate by histological methods the physical basis of delusions, but the neurologist now recognised that many of his own cases were purely functional and mainly mental.

The Rôle of the Psychiatrist.

These considerations led with a convincing directness to the important part the psychiatrist should play in the treatment of functional nervous disorders and borderland cases. Yet it could not be said that he occupied the position he ought in this respect. How many of our great hospitals had a psychiatrist on their staff? Undoubtedly the neurologist suffered as much from this divorce as did the psychiatrist.

There were three points of particular interest in the study of borderland cases from the psychiatric point of view. The first of these dealt with the possibility of suicide in patients with mental depression. Practically every melancholic was at some period of his illness a potential suicide. Moreover, the risk was greatest during the later stages of convalescence when the patient was least carefully watched, and had the best opportunities of committing suicide. Melancholia was the commonest form of psychosis and the least obvious departure from the normal. The melancholic patient was usually quiet, had some insight into his condition, and could talk sensibly on subjects unrelated to his depressive ideas. A patient suffering from melancholia was, therefore, a typical borderland case, and was also the most dangerous form of case, as far as danger to life was concerned, which a medical man could be called upon to treat. Therefore, the help of a psychiatrist should be called for in all doubtful cases of depression. Prof. Robertson suggested that were his audience to forget all that he said with the exception of the one statement that practically every patient suffering from melancholia was a potential suicide, even then his lecture would not have been given in vain. What added to the distress of the suicide of a melancholic patient was the fact that all healthy melancholics made good recoveries.

His second point was that of certification when a case ceased to belong to the borderland group. The law was not concerned with disease, but with conduct, and when this was so affected by disease of the mind that the patient was not fit to enjoy full liberty, then we had the medico-legal condition known as insanity. In melancholia the refusal to take food or remarks to the effect that life was not worth living might be valid reasons for certification.

The Emancipation of the Mental Hospital.

Finally, he entered a plea for the emancipation of the mental hospital and for the introduction of a new status for it. The Acts regulating the admission of patients into mental hospitals both in Scotland and England were antiquated in spirit and had outgrown their usefulness. They were now a curse which weighed heaviest on the poor. Why should not borderland cases, cases of mental disorders in their early and most curable stages, receive all the advantages of accommodation and treatment given in our modern mental hospitals, from which they were at present debarred by the necessity of preliminary certification and legal commission? Private patients were seeking admission voluntarily to such hospitals as Craig House in increasing numbers and exceeded the certified patients. They came at an earlier and more curable stage, one corresponding to the borderland case. If the lunacy laws were amended so that patients of small means could also enter mental hospitals for appropriate treatment, a new era of progress would be entered. Simple notification would provide all the legal security such patients needed. Then the borderland, which after all was merely an artificial legal distinction, would disappear, and our mental patients would be able to seek treatment without fear of the reproach which they now believed to attach to them.

Discussion.

Dr. IVY MCKENZIE (Glasgow), referring particularly to military cases, stated that the 1200 cases which had passed through observation wards under his charge might be divided into three categories: those in whom toxic factors predominated, those who were mentally defective, and a group of amnesic cases. The first two groups did not respond to any form of psycho-therapeutic treatment, and although they often expressed themselves as feeling better after it they did not return to work, which, after all, was the only test of value. In the toxic cases there was a history of some infection, the results of which needed treatment on ordinary general lines as a preliminary measure. The amnesic group responded to psychotherapy.

Dr. HELEN BOYLE (Brighton) emphasised the importance of unhappiness as a factor in the production of neuroses and psychoses. Unhappiness should be regarded as an abnormal condition and treated accordingly. If a patient's occupation in life was uncongenial and a source of discontent, he or she should be advised to change it for some more pleasant mode of life. General hospitals should contain special wards for borderland cases. The patients should not be subjected to the ordinary inelastic discipline, but should be kept amused and allowed considerable freedom in the matter of seeking occupation and amusement, and should have ample and special nursing care. No case was simple in its origin, but arose from numerous factors, hence no single method of treatment could be infallible. Rest in bed was an important factor in treatment.

Dr. BEDFORD PIERCE (York) said that such treatment as was suggested by the previous speaker was commonly impossible on the grounds of expense, and was certainly not accessible to the poorer classes.

taking the bite; the strength and rigidity of dentures; and the general methods of their retention. The author insists that dentures must be designed and constructed to avoid as far as possible injury to the gum margins, and we are pleased to see that he does not ignore springs as a useful method for retaining them. The work should prove of value to the practising dentist, who will find information therein which will help him to smooth away most of the difficulties he meets with in the adaptation of dentures.

Local Anæsthesia. Its Theory and Practice in Dental Surgery. First edition. By NORMAN BLACK, L.D.S. Eng., Lecturer on Dental Surgery and Pathology, Dundee Dental School. London: John Bale, Sons and Danielsson. 1921. Pp. 73.

COCAINE as an anæsthetic in dental surgery first came into prominence about the year 1887. The general use of the drug, however, fell into abeyance owing to the extreme toxic effects which at times followed its use. With the introduction of drugs with less toxic properties and improvement in the technique of administration, local anæsthesia has slowly gained in favour with dental practitioners. In this useful little book the author describes concisely the technique for the production of local anæsthesia by the infiltration or nerve-blocking methods. To the dental practitioner anxious to acquire a knowledge of local anæsthesia we can cordially recommend Mr. Black's excellent little book.

JOURNALS.

Journal of Pathology and Bacteriology, Vol. XXIV., No. 3, July, 1921.—Studies in Heterophile Antigen and Antibody, by T. Taniguchi. Tissues from a variety of animals will, when injected into rabbits, cause the production of hæmolytic immune body for sheep corpuscles. These heterogenic antigens occur in the guinea-pig, horse, dog, tortoise, &c., but not in the ox, pig, man, goose, frog, &c. Organs may contain them while the blood corpuscles of the same animal may not. The heterophile antibodies thus generated react with the lipoids of the tissues, especially the lecithin fraction, but these lipoids will not act as antigens nor will the proteid residue which remains after extraction of the lipoids, the natural proteid-lipoid complex being required.—On Acute Yellow Atrophy of the Liver and the Fatty Infiltration of the Liver and Kidneys which Results from the Action of Certain Poisons on the Liver, by A. G. R. Foulerton. The author describes material from three cases of poisoning by trinitrotoluene, seven cases by arsenobenzol compounds, and single examples poisoned by diphenylchlorasine, antimony tartrate, and corrosive sublimate. Analyses of fat are given, also estimations of the distribution of arsenic in the tissues where its high concentration in the suprarenals is noticeable.—The Development of the Female Phase of the *Leucocytozoon Syphilidis*, by J. E. R. MacDonagh. The author gives further details of the appearances which he interprets as being phases in the life-history of the parasite of syphilis.—On the Pathology and Pathogenesis of Spirochætosis Icterohæmorrhagica, by C. Basile. The author gives an account of the disease in guinea-pigs which adds little to the description in Martin and Pettit's monograph. He thinks the hæmorrhages are more important than others have supposed and that they largely account for the jaundice.—A New Method for the Staining of Bacterial Flagella, by the late H. G. Plimmer and S. G. Paine. The original must be consulted for the details of what appears to be an easy and successful method.—Notes on the Histopathology of Typhus Fever, by A. C. Stevenson and A. Balfour. A study of sections from five cases of fatal typhus in the Caucasus obtained by F. E. Reynolds, with a useful summary of the observations of others. Special attention is drawn to the single layer of mononuclear cells in the perivascular spaces in the brain. With regard to the discovery of Rickettsia-like bodies, the authors note that they have found small diplococcal forms which might well be the parasite only in the nerve cells of the cerebrum, the vessels of the brain and lung, the cells and vessels of the splenic pulp, and the Kupffer cells of the liver.—The Effect on the Guinea-pig of Deprivation of Vitamine A and of the Antiscorbutic Factor with Special Reference to the Condition of the Costochondral Junctions of the Ribs, by F. M. Tozer. An extensive histological investigation of the material used by Dr. Chick and her colleagues in their nutritional inquiries at the Lister Institute. Deprivation of fat-soluble or antiscurvy vitamin leads to marked changes in the bones, growth stopping, and the whole structure becoming depauperated. There is no definite difference in the mild cases; in scurvy, however, the changes proceed to complete disorganisation of the costochondral junction with much secondary fibrosis.—The Sizes of the Red Blood Cells in Emphysema, by C. Price Jones. Examining 20 normal persons, 22 cases of emphysema, and 15 cases of cardiac failure, the author finds by precise methods that the mean diameters of the red corpuscles are 7·2, 7·7, and 7·2 μ respectively. Statistical analysis shows that the difference is far beyond any error of the method. The cardiac cases show that the large size in emphysema is not due to increased acidity due to circulatory failure. In one case studied in detail it was found that the size fluctuated with bodily activity as it does in normal people.—The Lesions Produced in Rabbits by the Inoculation of Streptococci Isolated from Rheumatic and Other Lesions in the Human Subject, by W. W. C. Topley and H. B. Weir. The authors show that it is possible to produce in rabbits, by inoculation with streptococci derived from cases of acute rheumatism, lesions which reproduce many of the features of the disease in man, and that similar lesions may be produced by the inoculation of streptococci obtained from sources which there is no reason to associate with rheumatic infection. The authors discuss, but do not solve, the doubts which these observations raise with reference to the existence of a specific *Streptococcus rheumaticus* and a specific disease acute rheumatism.—A Rabbit's Kidney Affected with a Parasitic Mould, by F. J. F. Barrington.—Observations on the Wassermann Test, Using a Method of Prolonged Fixation at Ice-chest Temperature, by E. J. Wyler. The method is more sensitive, but there is apt to be a weak non-specific fixation.—On Heterophile Anaphylaxis, by T. Taniguchi. Symptoms apparently anaphylactic in character may be produced by injecting into guinea-pigs the serum of rabbits containing heterophile antibodies. The serum of some animals contains heterophile antibodies, hence it is possible that some cases of anaphylaxis may be due to the inoculation of antigens of which the individual has had no previous experience.—The Syphilis Precipitation Test of Sachs-Georgi, by N. Yoshinare. In 1575 parallel tests the answers coincided in 90 per cent., discrepancies are more numerous in treated (19 per cent.) than in untreated (7 per cent.) cases.—Differentiation of the Streptococci, by H. W. Crowe. Further examples to show the value of chocolate blood agar for which the recipe is given. The streptococci isolated from the roots of more or less healthy teeth are usually of several different kinds.—Diffuse Carcinomatosis of the Stomach with Metastases, by G. M. Findlay.—Aldehydes as Mordants in the Staining of Fats and Lipins, by J. Lorain Smith and T. Rittie. Formaldehyde, acetaldehyde, and benzaldehyde act as mordants in staining fats and myelin by Weigert's method. Pure solutions have no action, the presence of some polymerised aldehyde is necessary.—The Production of Purpura in Birds and Amphibia by Inoculation with Thrombocyte Antisera, by J. C. G. Ledingham and H. M. Woodcock. Sera prepared in rabbits by repeated doses of thrombocytes from pigeon blood cause local purpura when inoculated into pigeons and a great diminution in the number of thrombocytes in the circulating blood; this affords further evidence that these elements of the blood are homologous with mammalian platelets.

becoming traditions. Among the most fruitful of guiding principles was undoubtedly Jackson's theory of the dissolution of function in the nervous system. According to this, every case presented a dual symptomatology—negative or defect symptoms, and positive or release symptoms. These two groups, with a third small group of irritative symptoms, were commonly considered to include all manifestations of disease. Head and Rivers had added a phylogenetic factor to this hypothesis. They believed that the "lower levels of evolution" remaining after some destructive lesion represented what had been normal activities of the nervous system at an early stage of its phylogenetic development. Thus "protopathic sensibility" and the "mass reflex" were to be regarded as approximating to the normal sensori-motor reactions of some hypothetical primitive animal. In general, phylogenetic hypotheses were entirely speculative, and the view prevalent among continental neurologists that abnormal reflex reactions were reversions to arboreal activities of pre-human ancestors met with a not unexpected reply in Prof. Karl Pearson's view that our forebears were never arboreal in habit. The view that almost all bodily ailments were psychical in origin vied with the phylogenetic school of thought in present popularity. The confusion of psychological and physiological categories by those who sought to establish psychogenesis as the solution of all our difficulties often led to grotesque conclusions, such as that of Jelliffe who stated that the overflow of psychical "energy" into the "somatic pathways" of the nervous system led immediately to the lesions of disseminated sclerosis. In general, it might be urged that before we had recourse to the exclusively verbal resources of the psychologist in the attempt to determine the causes of disordered function in the nervous system, physiological factors should first be excluded.

As an example of the importance of physiological factors, the psychical and neurological symptomatology of anoxæmia were described. The sensitiveness of the nerve cell and synapse to oxygen deprivation had long been known, but had never been seriously considered by the neurologist as an important factor in the production of disordered nervous activity. Physiological experiment, confirmed by clinical experience, showed that the initial reaction of the nervous system to minimal grades of anoxæmia was the development of an increased excitability. Clinically, so-called "irritative" symptoms were often manifestations of this condition. A symptom-complex closely resembling that of tetany was readily produced in the normal individual by a short period of forced breathing, which resulted in a relative anoxæmia. The mass reflex of spinal man was considered as a phenomenon possibly dependent upon this cause, and it was pointed out that reflex responses could be obtained in the spinal animal under suitable grades of anoxæmia, which appeared identical with the mass reflex of man. In conclusion, it was urged that neurologists, despite the clamant exhortations of the psychogenetic school, could not afford to neglect physiological factors when attempting to determine the causes underlying disease of the nervous system, in favour of the allegories and verbal researches of clinical psychology.

Dr. CARVER read a paper on

Epilepsy from the Psychological Standpoint.

Our views on epilepsy had within recent years undergone considerable widening. Epilepsy was a syndrome rather than a disease, and the convulsion of epilepsy was no longer allowed to dominate our conception of the condition. The study of the epileptic personality had afforded much new and important knowledge and had shown that the epileptic might be recognised at an early stage of his malady before any convulsion had occurred. In the causation of epilepsy, psychological, physiological, anatomical, and other factors had all to be considered. The views of Pierce Clark were then discussed. The personality of the epileptic was characteristic. He was egocentric, selfish, erratic, and moody. It was impossible to predict his behaviour from day to day. The fit was a regressive phenomenon. In the treatment of epilepsy it was of the first importance to study the personality of the patient, who was essentially a mal-adjusted individual, and to help him to adjust himself to his environment. Treatment on these lines was full of possibilities, while the customary routine bromide treatment had little to be said in its favour.

Dr. DOUGLAS ADAMS (Glasgow) read a paper on

The Early Diagnosis and Treatment of Disseminated Sclerosis.

The colloidal gold reaction in the cerebro-spinal fluid was a test of early organic nervous disease of the greatest value. Disseminated sclerosis gave constantly a "paretic" curve. In the treatment of the disease he had obtained favourable results in some cases by the administration of novarsenobillon and by mercurial inunction, though as the observations were of less than a year's duration the possibility of remission apart from treatment could not be excluded. No ill-effects followed this antisyphilitic treatment. He had conducted some successful inoculation experiments in the sense that animals inoculated with material from human cases of disseminated sclerosis developed paralytic symptoms. However, no histological investigation of the lesions underlying the paralyses in the experimental animals had so far been conducted.

In a short discussion following this paper, Dr. FARQUHAR BUZZARD stated that he favoured antisyphilitic lines of treatment, especially in respect of arsenical compounds, for disseminated sclerosis. It was important that treatment should be long persisted in. In the matter of experimentally produced paralyses in inoculation animals, he thought that unless the specific lesion of disseminated sclerosis could be demonstrated no conclusions could be drawn from the clinical observation alone.—Dr. J. CRUICKSHANK (Aberdeen) stated that in a somewhat extensive experience of the colloidal gold reaction he had never found a positive result except in neuro-syphilis and disseminated sclerosis. To differentiate the two a Wassermann test must also be carried out.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the Committee held on July 12th 20 cases were considered, and £244 voted to 16 of the applicants. The following is a summary of some of the cases relieved :—

Widow, aged 70, of L.R.C.P. Edin. who practised in Somerset and died in 1917. Applicant was left quite unprovided for on the death of her husband, and was helped by a brother-in-law, but he is now dead. She has been living on her savings, and they are now exhausted. Two sisters allow her £36 per annum, and board and lodging cost 25s. per week. Voted £18 in 12 instalments.

Daughter, aged 61, of L.R.C.P. & S. Edin. who practised in Filey and died in 1895. Applicant lost all her belongings through a fraudulent solicitor. She used to earn a little as a journalist, but cannot get work now and appeals to the Fund to help her. Rent and rates £33 per annum. Voted £18 in 12 instalments.

L.R.C.P. & S. Edin., aged 70, who practised in London and Cheshire, but now unable to work owing to paralysis agitans. He is dependent on his wife, who earns £3 5s. per week as a clerk. They are living with applicant's father-in-law, who has a pension and who is also helpless, and pay £2 per week for their board and lodgings. Voted £26 in 12 instalments.

Widow, aged 68, of M.R.C.S. Eng. who practised at Southam and died in 1882. Owing to chest and heart trouble applicant has not been able to earn anything for the last five years. For the past two years she has been living on proceeds of the sale of the furniture; these have now gone, and applicant asks the Fund to help her. She has been living with a married daughter, but cannot do so any longer, and her son allows her £12 per annum. Voted £26 in 12 instalments.

Widow, aged 41, of M.B. Irel. who practised at Enfield and died in 1920. Applicant left with four children, ages 5 to 16. The second boy, aged 14, provided for by uncle. The eldest son, aged 16, is consumptive, and has just returned home from a sanatorium. Applicant has sold her furniture, and is now living in rooms. Since September, 1920, she has received £114 from investments. Voted £18 in three instalments.

Subscriptions may be sent to the hon. treasurer, Sir Charters J. Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

not explained, while the plumber and sanitary engineer and the medical officer of health have all to be considered here. There is no reference to any hygienic activity directed towards school habits, hours, and environment, the hygiene of learning and the effects of fatigue. But all the vast mass of knowledge which we are now acquiring ought to have its outlet, with practical results of greater importance than many things which will be catalogued in the school reports. For, at very large cost, much useful work has been started, and the inquisition of the Board of Education should mean that during the next five years an enormous advance will be made in the provision of such preventive measures as feeding, open-air schools, nursery schools, school baths, provision for the crippled, epileptic, and special scholars, as well as extension of curative measures in medical, surgical, and dental treatment, almost everywhere reported as being insufficient. The school nurse has proved herself, and should become, the general bond between the school and the home. And during the coming period of activity we may look for greater help from the public. Some may ask—Is all the official louse-catching worth the cost? Is ringworm the deadly thing some of the reports suggest? The answer is that only by making these preventable conditions prominent can the medical profession teach the public to help themselves. Doctors and parents should establish ideals and help each other to set up standards of reference and comparison. The standard of hearing, by the way, adopted in these reports seems to be hearing the forced whisper at 20 feet. This looks like a confusion between feet and metres. We do not want, however, to pick small holes in the official work, but rather to urge the Board of Education to think of large policies. We look to the Medical Department of the Board to establish standards and to plan work of permanent benefit to humanity.

Medical service for the growing child can be far too strictly confined by medical inspection and treatment, subordinate to officials. These will have other interests and be wanting in the expert knowledge required for the appreciation of the relations between modern medicine and hygiene and the education of the growing child. Generally speaking, the reports of the local medical officers of health show too little expenditure on real school hygiene, want of method in estimation and comparison, and too much outlay on the trivialities of administration, often, indeed, a mere cataloguing. Health of the people is a commodity which can be had if we pay for it. It can be bought cheapest in childhood. It is of more value than any other commodity to the people of these islands, who, on the average, pay so heavily in health and years of life for their industrial supremacy. The medical staff of the Board of Education have an enormous opportunity before them.

◆

The Proper Place of Embryology.

It may be said in a broad way that human embryologists differ from general embryologists in that the former deal mainly with organogeny, whereas the latter are concerned largely with questions of more general and evolutionary interest. In this way, and also because they have undergone medical training, human embryologists are ready to see the connexions between their observations and those of the clinician or pathologist. Sir Arthur Keith, in his popular lecture at Newcastle-upon-Tyne, delivered at the recent meeting of the British Medical Association, showed that the healing of wounds is not a manifestation of a power acquired during life, but of one that is inherent in us from the beginning, and inherited by us from the lowest forms. So he terms "evolutionary wounds" those clefts and hollows which are closed in and covered over during embryonic life—a bold terminology at first sight, but one of which the essential justness becomes apparent after very little reflection. Embryologists must be struck by the similarity between the processes they are watching and those which, occurring at a later period in life, are termed pathological; but, as a rule, the matter ends there. For, owing to our ignorance of the causes which underlie growth and development, the observations are worth little save perhaps for the bolstering up of some theory. The phenomena of growth are dependent on much beside mere contiguity and mechanical processes, and we know practically nothing of these other factors. They appear to have some relation to those of regeneration, such as we see in lower vertebrates, and this faculty seems to be merely a modification of the more generalised power of complete regeneration which is found in certain invertebrates and among plants; it is, therefore, a very old property of living organisms, and one which, traced back, is apparently connected with the foundations of development of the whole body. Perhaps, then, this power, which Prof. Keith so admirably describes in a suggestive address, may be a modern representative of the force making the double embryo of the divided echinoderm egg; or we may even come to look on the scar of the amputation line as the equivalent of the regenerated limb of the dismembered newt.

But such pleasant fantasies do not help us very much in the day's work, nor have they (as yet) any practical bearing on the consideration of disease or injury by the pathologist. It is not so, however, with the matters of fact and observation which formed the basis of Prof. Keith's lecture, and they make a strong plea for closer coöperation between the embryologist and the pathologist. The student, or the work-a-day doctor, has little idea of the value of embryology among the foundations of pathological anatomy; it is fairly safe to say that, with the exception of such things as hare-lip and cleft palate, spina bifida, or certain malformations of the external genitals or of the heart, he does not trouble to recognise the existence of any connexion between developmental and pathological processes and conditions. He may, if pressed on the matter, go so far as to admit the possibility of a "developmental failure" or something of that sort, but he has no clear idea of what he means or implies by the phrase. Yet it might be said with some justification that embryology has at least as much to do with a comprehension of pathological anatomy as any other single science. It would be good for pathologist and embryologist to work together for the advancement of both; the pathologist might have some light thrown on dark places, and the embryologist would be encouraged to proceed with his elucidation of detail to definite purpose. Thus between the two the inquiry could be pushed back a step or two, even though there would remain for solution the innumerable mysteries of life and its reactions.

A necessary preliminary to this is that the teaching of embryology in the schools should undergo a change, and the dreary subject which goes by that name in examinations be altered to some purpose and made into a live study. Practical courses in embryology must go further than casual investigation of the segmentation of a frog's egg and the early stages of the private life of a chicken, and the student in general and in detail on the whole of present-day asylum administration, it is relevant to inquire with what equipment the author addresses himself to his task. Dr. Lomax is not a regular member of the asylum medical service; he tells us himself in his preface how he came to be interested in asylum work. A life-long student of psychology, and having retired from general practice, he applied when war broke out for employment in a large county asylum, at which he remained for two months, being transferred later at his own wish to a second asylum, one of the largest in the country, where he remained for nearly two years, his fellow officers being a Dutchman, an Australian, and an Irishman. It was therefore as a medical man of mature age and without special experience that he approached asylum life. The book is addressed to the general public, and would, he says, have been very differently written had it been addressed to the medical profession.

Dr. Lomax freely admits that those concerned in asylum administration have themselves regretted the grave defects and abuses which have crept in, but which cannot now be rectified without far-reaching administrative and legislative reforms; and he mentions especially the valued work of the Medico-Psychological Association. The delay in carrying out reform he attributes to lack of cognisance of the facts on the part of the public, and to their ignorance of the reasons for its necessity. The author divides his book into ten chapters, dealing first with asylum administration in general and the problem of insanity, going on to describe in detail the wards and general asylum routine, the various forms of restraint, the system of workshops and outdoor labour, the dietary of the inmates, the position and duties of the medical superintendent, the status of the assistant medical staff, the attendants and other officials, concluding with two chapters of a constructive character in which he sets out the legislative reforms which he desires to see and the ideal asylum as it might exist when these reforms have been carried out. When the book was written, shortly after the conclusion of the war, the author hoped that these reforms were within the range of practical politics, but he now fears they must perforce be relegated to more peaceful and prosperous times.

We need not quote in detail the author's indictment. He simply describes in plain terms what he saw and heard during his office, and assumes it to be typical of asylum practice. If this is so, asylum patients in winter are allowed to get wet in the airing courts, they have no overcoats, and the increase of bronchial and rheumatic affections is due to preventable exposure. Patients are isolated for punitive purposes by the attendants. Croton oil in 2-minim doses is the recognised method of taming troublesome or refractory cases. To the author, in fact, the whole system of pauper asylum administration in this country—he admits exceptions in the case of individual asylums—exists to detain and restrain demented paupers, never, except accidentally, to treat and, where possible, cure them. Dr. Lomax apparently overlooks the fact that the Board of Control exists primarily for protecting the liberties of the insane patient and not to deal with his treatment. Suggestions in regard to the latter can be made to the visiting committees, but it rests with them whether they are followed or not.

Dr. Lomax's proposals for legislative reform include the abolition of the word "lunatic," the provision of treatment for the early stages of insanity without certification, the revision of the constitution and power of visiting committees, drastic curtailment of the authority vested in the medical superintendent. The administrative reforms recommended include the gradual conversion of the barrack into the villa or cottage system, the appointment of a visiting medical staff, a more comprehensive and varied dietary, provision of open-air and isolation treatment of consumptive cases, revision of the rules for keeping case-books, and a more comprehensive use of parole in suitable cases.

Dr. Lomax's indictment of asylum administration is severe in the extreme. We should hesitate to accept much of it as an uncoloured statement of personal observation did it not agree in important respects with the contents of a pamphlet entitled "Life in a Madhouse" (National Labour Press, price 3*d.*) from the pen of a war-time male attendant. Allowance must be made for the painful impression made on untutored minds by continued contact with the saddest forms of human experience. We can hardly doubt either that inquiry will follow or that it will be welcomed by asylum superintendents, many of whom know the value of public interest and are anxious that all the facts of asylum life shall be properly appreciated. Some of the author's statements may prove to be unfounded except as isolated occurrences. Others may rest on false deductions, but enough remains to justify a searching inquiry, which cannot fail to benefit both the medical staff and the sick poor under their care.

AMŒBOID MOVEMENT.

By A. A. SCHAEFFER, Ph.D., Professor of Zoology, University of Tennessee. Princeton: University Press. 1920. Pp. 156. 10*s.* 6*d.*

IN this readable volume the author has collected together a great number of observations, mostly made by himself, on the mode of locomotion in the different kinds of amœbæ. The streaming of the endoplasm is regarded as essentially the same phenomenon as the streaming which is familiar in plant cells. A special result of this streaming is the formation of a temporarily differentiated ectoplasm which, while not necessarily resulting from streaming, is essential for locomotion. Outside the ectoplasm is a third layer, functionally if not morphologically distinct from ectoplasm, whose existence is best studied by watching the movements of extraneous particles that have stuck to it; this "surface layer" moves independently of the ectoplasm and of the animal as a whole, and is activated by changes in surface-tension. From a very large experience in observing their behaviour the author seems loth to believe that the amœba is an automaton whose activities are demonstrably due to external stimuli, and he appears to be inclined to give it credit for a tolerable amount of intelligence and free will. Interesting observations, illustrated with good diagrams, lead Prof. Schaeffer to the conclusion that the wavy path of the amœba's progress represents a projection of a helical spiral on a plane surface. He extends this by observations on ciliates, spermatozoa, flagellates, blindfolded swimmers and walkers, to the generalisation that moving organisms in which orientating organs are absent or not functioning always move in orderly helical or true spiral paths. The route of the amœba is made up of segments of circles, and is strikingly similar to the tracks which men make in their attempts to regenerate footpaths straight across newly ploughed fields.

DENTISTRY.

Prosthetic Dentistry. A Text-book on the Chair-side Work for Producing Plate Dentures. First edition. By DOUGLAS GABELL, L.R.C.P., M.R.C.S., L.D.S., Dental Surgeon to the Royal Dental and Charing Cross Hospitals. London: Henry Frowde and Hodder and Stoughton. 1921. With 58 illustrations. Pp. 237. 12*s.* 6*d.*

THIS book "deals with the chair-side work for fitting ordinary dentures in the natural order for such work, discussing each step as it is taken," and it is the outcome of the author's many years' experience as a practitioner and teacher. The book opens with an excellent account of the indications for and against removable and fixed appliances. There are chapters on the methods of obtaining impressions of the mouth;

at operations in the Mayo Clinic between January, 1910, and July, 1920. During this time 4189 fibromyomatous uteri were removed, of which 332, or 7·9 per cent., contained adenomyomata. Dr. Mahle regards von Recklinghausen's theory of the origin of tubal adenomyomata from the Wolffian and Müllerian ducts as untenable, and considers that these tumours are the end-product of an inflammatory process. Of the 23 cases, 5 were associated with acute salpingitis, 6 with tuberculous salpingitis, 1 with hæmatosalpinx, 1 with ectopic pregnancy, and 1 with papillary carcinoma of the ovary. All the cases showed some evidence of pelvic inflammation, such as cystic ovaries or pelvic adhesions. The tumours were situated in the proximal end of the tube and isthmus, and appeared as small swellings ranging from a slight thickening of the wall of the tube to a mass 1 to 2 cm. in diameter. The process as a rule was circumscribed, though in one case it extended throughout the whole length of the tube. Twelve, or 52 per cent., of the tumours were bilateral, 7, or 30·4 per cent., were on the right side, and 4, or 17·4 per cent., were on the left. The average age of the patients was 37½ years, the eldest being 64 and the youngest 17 years. 34·7 per cent. gave a history of previous pelvic inflammation. The relation between sterility and the presence of these tumours was shown by the fact that 15 of the 23 patients had never been pregnant, 18 had never given birth to a living child, and of the 5 who had borne children only 2 had had normal pregnancies.

ARABIAN MEDICINE.

THERE are few periods of medical history more interesting or about which less is known, save by professed students, than the Arabian period or body of Arabian Medicine, by which is meant, as Dr. Edward G. Browne says in his book on this subject,[1] "that body of scientific or medical doctrine which is enshrined in books written in the Arabic language, but which is for the most part Greek in its origin, though with Indian, Persian, and Syrian accretions, and only in a very small degree the product of the Arabian mind." It is to Arabian medicine that we owe the keeping alight of the flame of scientific and medical knowledge during the interval between the decay of Greek learning—i.e., about the seventh century—and the Renaissance; for though Hippocrates and Galen had been translated into Latin as early as the sixth century, the translations disappeared, and European knowledge of Greek medicine was, during the period A.D. 700 to the fall of Constantinople, entirely derived from Latin translations of Arabic or Syrian translations from the Greek. Hence the importance of the period with which Dr. Browne's lectures deal. The golden age of Arabian learning culminated in the century between A.D. 750 and 850, under the Abbasid Caliphate at Baghdad, and about the same time the great school of Gondisapor in Persia attained its highest glory. From Gondisapor came the great translators Hunayn and Hubaish, and there, too, flourished the well-known medical family of the Bactishuas. By the labours of these translators, Hippocrates, Galen, Oribasius, Rufus of Ephesus, and Paul of Ægina were made known to the Moslem world.

In his second lecture Dr. Browne devotes himself mainly to an account of four great Persian medical men—namely, Ali ibn Rabban, Rhazes, Haly Abbas, and Avicenna. Ali ibn Rabban was the author of the Paradise of Medicine, a book which the author says contains "the greater part of what the young graduate needs of the Science of Medicine." Dr. Browne explains his use of the term "graduate" as a translation of the Arabic word *mutakharrig* by telling us that a qualifying examination in medicine did exist in the year A.D. 931, even if it did not in A.D. 850, when Ali ibn Rabban wrote. The examination was not particularly searching, as may be seen by Dr. Browne's account thereof; but after all it was but slightly easier than Mr. Roderick Random's examination for a surgeon some 800 years later. Of Rhazes and his works and writings Dr. Browne gives a most interesting account, though we are rather surprised to see that in mentioning Rhazes' well-known monograph upon small-pox and measles, and the translations thereof, he makes no mention of what we believe is the earliest English translation—namely, that by Dr. Mead, translated from the Latin in 1747. The Arabic version was sent to Mead by Boerhaave transcribed from a MS. in the University of Leyden. Mead gave this transcription to "two gentlemen of character," who produced two Latin versions, which, however, differed so much that Mead applied to Dr. Thomas Hunt, Professor of Arabic in the University of Oxford, who collated the two Latin versions with the Arabic and supplied Mead with the version which he translated. In his notice of Haly Abbas Dr. Browne quotes some excellent remarks of that physician on the importance for a medical man of regular attendance at the hospital, whereby he will reach a high degree in the art of medicine. Haly Abbas's great work was the Maliki or Liber Regius, which enjoyed great popularity, until the appearance of Avicenna's Canon, which overshadowed it. Avicenna is still, or was at least so late as 1888, held in great reverence by Persian physicians, as we know by personal experience.

Dr. Browne's third and fourth lectures are devoted to a consideration of Arabian popular medicine, medical anecdotes in Arabic and Persian literature, together with various delightful stories about Rhazes and Avicenna and the use of psycho-therapeusis. There is also a story about two court physicians whose rivalry reached to such a pitch that they agreed to a duel in which each was to take a poison supplied by his rival, the effects of which he should counteract if he could by an antidote. Accordingly, physician A gave physician B a powerful poison, which B swallowed and immediately afterwards took an antidote which he had prepared which rendered the poison innocuous. Physician B then picked a rose, breathed an incantation over it, and gave it to physician A to smell, which he did and at once fell down dead, as the poet who relates the tale says: "Fear overmastered the foe, and he gave up the ghost." Had Pope heard this tale when he wrote in the Essay on Man:

> "Or quick effluvia darting through the brain
> Die of a rose in aromatic pain"?

Lecture IV. gives an all too short account, as Dr. Browne confesses, of the brilliant civilisation in Spain and the West under Moorish domination, and of the many and admirable hospitals established throughout Moslem lands during the Middle Ages, the greatest of which was perhaps that built at Tabriz in the thirteenth century by Rashidu'd-Din-Fadlu'llah, born A.D. 1247. Many of his letters about the hospital are quoted, and the book ends with a description of the principles of Arabic medicine.

We have read the lectures with very great pleasure, and can only express a wish that Dr. Browne will follow them with an account of Moorish medicine in Spain, for the Moorish domination there during the twelfth and thirteenth centuries was marked by extraordinary intellectual brilliancy, by fostering of learning, and by a toleration of religions other than that of Islam which puts Christianity to shame.

PHYSIOLOGY AND PATHOLOGY OF THE KIDNEY IN SUCKLINGS.

IN the *Wiener Medizinische Wochenschrift* of June 18th Fritz Wengraf makes a contribution to this subject. He recalls first the observations of Aschenheim and Ohlmann that in the first four months of an infant's life there obtains a peculiar metabolism as regards the salts and water—viz., that the water taken

THE LANCET.

LONDON: SATURDAY, AUGUST 6, 1921.

The Prevention of Tubercle.

A NOTEWORTHY feature of the important Conference of the International Union against Tuberculosis, held in London last week and briefly reported on p. 301, was the comparatively little attention paid to treatment by those who contributed to the discussions. Questions of racial incidence and immunity and measures of prevention occupied pride of place. The views of Colonel G. E. Bushnell, Prof. S. Lyle Cummins, and others, who see in tuberculosis "a disease of civilisation," as Prof. Calmette expressed it, are well known, though, for our part, we prefer Sir Robert Philip's description of tuberculosis as "a vicious by-product of an incomplete and ill-formed civilisation"; for a by-product of civilisation is by no means the same thing as civilisation itself. The art of modern medicine consists, as does the art of the chemist, in the elimination of superfluous and harmful by-products, and if the worker in tuberculosis could only determine experimentally the exact conditions upon which results depend, and eliminate or control those which give rise to useless by-products, civilisation might still be allowed to pursue its tranquil path. Great interest attached to Dr. Armand Delille's exposition of the "boarding-out" system of Grancher. All speakers were agreed that infection with the tubercle bacillus takes place in the majority of instances in childhood, and that the clinical recognition of such infection is frequently impossible. But, given the manifestation of certain stigmata associated from time immemorial with tuberculosis, reinforced by a more or less definite sensitiveness of the skin to tuberculin, we may presume the presence in the child of a focus of active disease—it may be insignificant and occult—and take measures accordingly to prevent further development. Grancher boarded these children out with families in the country, paid for their maintenance and education till they reached adult age, and trained them for occupations which they could afterwards follow. Under these favouring circumstances no one would question the likelihood of good results. The doubt alone is how far such a system can be made applicable to an infantile population, the great majority of whom are infected, and the great majority of whom, it must be added, are, even under unfavourable circumstances, not going to develop tuberculosis in an active and clinically recognisable form. The separation of children for long periods from their parents, apart altogether from the difficulties of inducing the latter to bear their part of the expense involved, raises questions of moral and legal import demanding careful consideration ere such a scheme were to be embarked upon in this country on a scale commensurate with its importance. An extended application of the open-air school system would probably do much to tide children over the danger zone between occult infection and florid disease, and it is obvious that the Grancher system must, if it is to succeed, be a matter for the State, since those whom it involves are all or nearly all of school age.

In his lucid summary of State action in the prevention of tuberculosis, made at the Conference, Sir George Newman laid great stress on the necessity of after-care. We incline to think the prefix "after" might now be omitted, for the problem involves not only the care of the patient after completion of his institutional treatment, but the care of the family and dependents during or even preceding the treatment, as reference to the records of the admirable Care Associations in existence will readily demonstrate. How far the State should intervene in this matter is an open question. The principle of administering voluntary funds through the medium of the tuberculosis officer and his nurse, without the stigma of charity and the inevitable catechism of officialdom, is working smoothly enough in practice, and so long as the grants are considered only as supplementary to those already given under the Insurance Act by the county councils, and by the Poor-law and other authorities, the distribution might well be left to the voluntary associations as at present constituted. But this subject, important though it is, was but an interlude in the Conference, the key-note of which was the prevention of tuberculosis, wherein lies the great hope for progress in the future. Treatment remains at best merely palliative, an attempt to limit and circumscribe the damage which the horse may be expected to inflict when it escapes from the stable before we have had a chance to lock the door. It is true that some of the most eminent investigators in tuberculosis seem to have reached the point of gloomily surveying the prospect and propounding questions to which they are only able to answer, "We do not know." None the less, whether we know the reason or not, a study of the death-rate from tuberculosis during the last thirty years suggests that it is a moribund disease.

◆

School Hygiene.

THE annual reports of the officers of the School Medical Service are now being issued, and show the increasing interest and effort being manifested on behalf of the children. The reports are appearing in all sorts of shape and size, and once again we must point out how much convenience would be served if a uniform format could be adopted. This should be the easier because the Board of Education have lately issued instructions to school medical officers regarding the contents of their annual reports, showing that information is sought which can be compared and collated. If such information arrived in a shape which allowed of filing or binding, it would be available as long as it was pertinent. In the words of one of the officers, "these instructions of the Board constitute in effect a species of school medical catechism, and I find it particularly difficult to answer this catechism to the satisfaction of the Board, and at the same time to write a report which shall be readable and instructive to the Education Committee and the public." We sympathise with the obvious difficulty, but the issue of the questionnaire is an excellent move on the part of the Medical Department of the Board, for the answers show up lacunæ in the service, and also help us to become aware of much ignorance not only in remote villages but also in high places.

The first important heading asks for a general report on "school hygiene," the scope of which is of the total non-protein nitrogen constituents of the blood in 55 patients with arterial hypertension in whom there was no clinical evidence of nephritis. He comes to the conclusion that there is a disease, arterial hypertension, which when uncomplicated by nephritis or cardiac decompensation gives no functional evidence of kidney insufficiency, and that the height of the blood pressure bears no relation to the amount of non-protein nitrogen substances in the blood. In short, the application of micro-chemical methods of blood examination to certain cases of arterial hypertension fails to convict these cases of chronic nephritis, and in the meantime they may be properly classed under the rubric of hyperpiesia. In any serious attempt to investigate the non-protein nitrogen content of the blood in hyperpiesia, such conditions as chronic nephritis, heart failure, gout, diabetes, and malignant disease must be excluded, since these diseases are known to influence the non-protein nitrogen in the blood. Yet the 55 patients examined by Dr. Williams had only one clinical feature in common—namely, hypertension—and in other respects form a motley group. Though it is stated at the outset that his patients had no clinical evidence of nephritis, in a later paragraph he speaks of evidence in some of the cases of renal impairment, and a significant proportion were clinically diagnosed as chronic nephritis; there are also included cardio-renal cases, patients with heart failure, arteriosclerosis, tertiary syphilis, diabetes, cirrhosis of the liver, gout, and chronic arthritis. The subject is one of considerable difficulty. Arterial hypertension is not a disease, though it may be a sign of disease, and for the elucidation of the problems it presents uncomplicated cases should be selected for investigation. Further, it is not statistics of 50 or 100 cases that are required so much as detailed clinical records of single cases combined with adequate records of renal function tests and blood analyses, followed, if possible, over a period of years, and finally completed by post-mortem examination with the application of modern histological methods.

X RAY TREATMENT OF ENLARGED TONSILS.

Chronic hypertrophy of the tonsils is a condition which has excited little interest in medical circles except among the few, and has been the subject of active interference rather than pathological study. Probably this is because the disease is so common and the material available for investigation so abundant, for it is always the minor malady which is regarded as inevitable and as offering but a limited field for research. We should hesitate to hazard a guess as to the proportion of tonsils removed by operation which are submitted to microscopic examination, but it must be surprisingly small, among quite the minor decimals. Nevertheless, the condition seems to merit more careful consideration. In the *Archives of Internal Medicine* for June, Dr. Carl Vernon Weller records the results of the routine histological examination of tonsils removed by operation from patients of either sex and varying age. Nearly 9000 consecutive cases were examined, and of these 2·35 per cent. were found to be tuberculous. The incidence of tuberculosis in the tonsil is about equal in the two sexes, but it is particularly high in institutions for the care of children, and among nurses, students, and interns in hospitals. In children the organism is usually of the bovine type, and this probably explains the type of tissue reaction found, for this is essentially chronic, and caseation is rare. In adults the infection is more commonly of the human variety, as anyone would suppose who has examined his nasal secretion after a morning spent in the routine clinical investigation of phthisical patients.

Another aspect of the subject is dealt with by Dr. James Murphy and his collaborators in the *Journal of Experimental Medicine* for the same month. It is established that X rays have a selective destructive action on lymphoid tissue, and the authors have utilised this knowledge in the treatment of enlarged tonsils. With carefully graduated doses of rays they have brought about shrinkage of the tonsils and eversion of the crypts, with emptying of their septic contents. The cure thus brought about is apparently permanent, and the treatment may safely be applied to the ordinary chronic septic tonsil, since the infection is limited to the crypts which, on account of the shrinkage of the lymphadenoid tissue, appear to be mechanically everted and drained. Whether this treatment is equally suitable for tuberculosis of the tonsil is another matter. It is true that, according to Dr. Weller, some 60 per cent. of tuberculous infections of the tonsil are crypt infections, with no involvement of the lymph follicles themselves, but inasmuch as the lymphocyte appears to be particularly concerned in the tissue reaction to the tubercle bacillus, the wisdom of destroying it may be open to question. This point will, no doubt, be settled by further work, and in the meantime it is satisfactory to learn of a method of treatment which appears to have considerable advantage over the usual surgical procedures.

THE MODE OF ACTION OF KAOLIN.

The successful use of kaolin in the treatment of cases of Asiatic cholera, described by Dr. R. R. Walker in our present issue, is of great interest, although, as Sir Leonard Rogers pointed out at the meeting when the paper was read, the results cannot be regarded as quite conclusive in view of the comparatively small number of cases treated. Dr. Walker explained at the time that when administered by mouth kaolin was inert and insoluble and did not pass into the circulation. He attributes great importance to the action of kaolin in removing toxins, and the possible value of the drug in bacillary dysentery is not escaping attention. It is necessary to consider the fundamental chemical details concerned in Dr. Walker's experiments to arrive at a tentative explanation of the action of kaolin. Proteins, which consist of a "mixture" of 18 to 20 amino acids, are acted upon by bacteria in various ways; in the case of putrefaction, amines may be produced by the loss of carbon dioxide from the amino acid. Except histamine from histidine, tyramine from tyrosine, and indol-ethylamine from tryptophane these amines are not very toxic. The toxicity of histamine and the rest is not comparable with the toxicity of the real bacterial toxins, and it is probable that these are more complex protein derivatives of the nature of a polypeptide or simple peptone, containing in its molecule one of the toxic amines, in cholera perhaps indol-ethylamine. Cholera vibrios are identified amongst other tests by the "indol" reaction—i.e., by the production of indol itself or some simple indol derivative from tryptophane. Indol and its simple derivatives, such as indol-acetic acid, which have a slight toxic action, are not absorbed by kaolin, but the complex toxin is absorbed. The absorption probably occurs by the mutual precipitation of oppositely charged colloids, the kaolin and polypeptide. The actual effect of the kaolin in the intestine is thus most likely to be one of adsorption. For a mechanical action it would be necessary to conceive the whole of the absorbing mucous membrane of the intestine being covered by the kaolin so as to prevent the passage of the poison.

Sir Ernest Hodder-Williams, C.V.O., has been appointed a Knight of Grace of the Order of St. John of Jerusalem in England, and Dr. James Woodward Riley has been appointed an Esquire of the Order.

INDEX TO "THE LANCET," Vol. I., 1921.

The Index and Title-page to Vol. I., 1921, which was completed with the issue of June 25th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of The Lancet, 1 and 2, Bedford-street, Strand, W.C.2.

ought to be seriously examined on actual developmental detail. The arid statements of embryologists—mainly German—of the last generation but two, once they have been shown to be wrong in part or altogether, ought to be scrapped remorselessly, and a student who brings out some developmental statement which is known to be untrue ought to be dealt with on the lines which would be apportioned to one who maintained some pre-Harveian view of the circulation. At present, the teacher who is a competent embryologist hesitates to put his information before his students, partly because it would almost be a waste of precious time, things being as they are, and the "embryology" of the syllabus being mostly a farce; and partly because he knows that his students may at any time run up against an examiner whose antediluvian views on the subject may lead to their confusion. Thus the standard of embryological teaching is practically set by those who are not embryologists and do not recognise the differences between the embryology of to-day and that of their youth. Many examiners would be glad to see the semblance of embryology removed from the examinations if the subject cannot be properly and systematically dealt with. We imagine that few of the general run of medical students could form a mental surface-picture of the very simple developmental processes so clearly and shortly described by Prof. KEITH, although they will be expected, at a later stage in their studies, to talk with some appearance of knowledge about the developmental affections of the regions concerned. This is not as it should be, and the fault can only be met by giving embryology its proper value in the curriculum. General embryology ought to be an important part of the biology course through which each student must go, and human embryology should be an equally—or more—important part of his anatomy course; then his pathology would be firmly based on physiology, anatomy, and embryology, with bacteriology, and thus a good foundation would be laid on which to erect a clinical superstructure.

◆

FACTORY HYGIENE IN 1920.

No evidence of the rapid progress which is taking place in the human side of British industry is more direct than that afforded year by year in the Reports of the Chief Inspector of Factories. These reports in recent years have not only told of important progress made, but have been presented in a more interesting and readable form than formerly. Even the size of the report now before us (H.M. Stationery Office. Cmd. 1403. Price 1*s.* 6*d.*) is changed; it is no longer a cumbrous blue book, but a pamphlet of which brevity, clearness, and human interest are the distinguishing features. The reader cannot fail to be amazed at the complicated code of legal requirements, orders, and regulations which have to be administered, and at the intricate knowledge of multifarious industrial processes needed for carrying on the work. Mr. R. E. Graves tells how the feverish boom in trade which followed the great war extended into 1920, only to give way to a remarkable depression before the year was over. The tendency for small workshops to disappear before large factories has been marked; there were 3766 fewer workshops and 4610 more factories than in 1919. New developments are referred to: the village van and cart builder is converting himself into a motor repairer; a dead meat industry on American lines is appearing at Drogheda; improved utilisation of water power for a woollen mill near Edinburgh marks an interesting advance; and in the Midlands there has started an engineering works managed and staffed solely by women. To the hygienic aspect of these remarkable developments we shall have occasion to return.

Annotations.

"Ne quid nimis."

LOCAL VOLUNTARY HOSPITALS COMMITTEES.

THE *Voluntary Hospitals Commission* has shown no delay in getting to work. Letters have been addressed to the clerks of county councils and county boroughs in England requesting the assistance of the councils in the constitution of Local Voluntary Hospitals Committees, as recommended by the Cave Committee. As a general rule the county, with those county boroughs situated within it, will be taken as a unit; but the larger county boroughs will be constituted units by themselves, and some of the counties containing but few hospitals will be combined into one area. Should there be a general consensus of local opinion that local circumstances are such as to call for variation of this scheme, alternative suggestions emanating from the area will be considered. Separate arrangements on analogous lines are being framed for Scotland and Wales.

As a rule the Local Committees will consist of two members nominated by the county councils, and one by each county borough within the county. There will be two medical practitioners nominated by the local medical committees in the area, one to be on the staff of a voluntary hospital and the other a general practitioner; and two hospital representatives not medical practitioners, one for the larger general hospitals and one for the smaller and cottage hospitals in the area. The Commission will nominate not more than five additional members from among those resident in the area, one at least of whom will be a woman, and the Local Committee will select its own chairman from among its members or from outside. The functions of the Local Committees will include the following:—

(*a*) To act as local advisers to the Commission.
(*b*) To collect information as to the needs of their areas.
(*c*) To further coöperation between hospitals.
(*d*) To coördinate appeals.
(*e*) To consider the possibility of arranging the transfer of patients where this can advantageously be done.
(*f*) To prepare, where practicable, schemes of coöperative purchase.
(*g*) To advise as to the adoption of a uniform system of hospital accounts throughout their area.
(*h*) To organise systematic contributions both from employers and by employees in areas where no such systems at present exist.
(*i*) To undertake the distribution of any contributions made by an approved society in cases where the society is purely local in character.
(*j*) Generally to take every possible step to assist the hospitals in their area to maintain the present voluntary system.

Local Committees will also consider generally the existing provision of hospital accommodation in their area. For this purpose the Commission has adopted the following definition of a voluntary hospital:—

> An institution (other than an out-patient dispensary) managed by a responsible committee, and wholly or mainly supported from voluntary sources (including income derived from endowments or investments), the object of which is to provide medical or surgical treatment of a curative character; an auxiliary institution (such as a convalescent home) being eligible for assistance only in so far as it increases the facilities of hospitals from which it receives patients.

In the metropolitan area the King Edward's Fund will act as the Local Committee, and will be responsible for advising the Commission on applications from voluntary hospitals within the nine-mile limit, which is the area now covered by the operation of the King Edward's Fund.

ADENOMYOMA OF THE FALLOPIAN TUBE.

DR. Arthur E. Mahle,[1] of the Section of Surgical Pathology of the Mayo Clinic, reports 23 cases of adenomyoma of the Fallopian tube which were found

---

[1] Surgery, Gynecology, Obstetrics, July, 1921.

20 branches, and it was hoped to have one in each of the 89 Departments, as the Government gave a large grant to the work.

A Hastings delegate said the system had been tried in his district with great success for some years. He did not know of a single failure.

Sir **ROBERT PHILIP** said the system was sound.

In the evening a reception was held by the LORD MAYOR of LONDON at the Mansion House.

WEDNESDAY, JULY 27TH.

On Wednesday morning the Conference discussed the subject

The Modes of Diffusion of Tuberculosis throughout the Races of the World.

Prof. J. **CALMETTE** (Pasteur Institute, Paris) read a paper in introducing the discussion, in which he said that since 1908 certain diagnostic methods had enabled the bacillus of tubercle to be detected in the human body even in the absence of clinically ascertainable lesions, and this had made possible a general survey of populations and the ascertaining of what proportion were infected with the disease. The most practical method to date was that of von Pirquet, of Vienna—i.e., two slight skin abrasions over the deltoid and the introduction of a small drop of tuberculin, either pure or in a 1-in-10 dilution. The postitive indication was the occurrence of a papule at the site of scarification in 10 to 24 hours. After remaining 5 or 6 days it completely disappeared. Before the war it was found that in certain countries tuberculosis was either absent or very rare, such as in Equatorial Africa among tribes where civilisation had not been introduced. But in cities and civilised communities of all climates the disease was very prevalent. Statistics showed that tuberculosis among the civilised nations of the world gave an average of 12 per cent. of deaths, and in the most favoured countries—Belgium, Italy, Portugal, Spain—the figure was 7·4 per cent. of deaths. As to the proportion of people in very large cities who showed a positive infection, as contrasted with having the established disease, 20 per cent. of the children were found to be infected at 2 years of age, 55 per cent. at 5 years, 90 per cent. above 15 years, while 97 per cent. of adults gave a positive reaction to tuberculin! In the country districts tested the figures were very much lower. In countries possessing many races there were marked differences in attack-rates, probably due to the length of time the disease had been implanted in them, and to some extent referable to the habits of life. Peoples who had been longest isolated from the disease proved to be the most susceptible to it when brought into infected communities. Civilised races, on the other hand, were more resistant owing to the comparative immunisation due to long infection. "In man, therefore, tuberculosis results from his civilisation." The same was true of cattle. The spread of tuberculous infection throughout the world was due to disseminators of virulent bacilli, who were often apparently healthy carriers. It had been shown by the author that bacilli injected into the blood stream were eliminated through the bile passages. The author quoted a number of independent investigations by other workers which established the same fact. Titze had shown that when tubercle bacilli were injected intravenously into a lactating cow they began to appear in the milk towards the third week. Carriers of tuberculosis who were apparently healthy might have lesions limited to a few glands, and from these be continually infecting new subjects. Protection of children and the general population in countries comparatively free from the disease could only be contemplated on the condition of reorganising a system of detection based on the judicious use of tuberculin tests and a clinical examination of the glandular system, based mainly on radioscopy.

Bovine Form of Infection.

Sir G. **SIMS WOODHEAD** (Cambridge) spoke on the diffusion of tuberculosis in the human subject through infection with the bovine form of the bacillus. It was clear that geographical considerations had much to do with the arguments brought forward with regard to the spread of tuberculosis. In Japan, for instance, the bacillus of the human type played a much more important part in the process of infection than it did in Edinburgh. At an early stage of the inquiry 30 per cent. of the cattle in Edinburgh dairies were found to be tuberculous, and in 16 per cent. of the samples of milk being distributed to certain areas tubercle bacilli were found, often in considerable numbers. A large number of the children who died from tuberculosis had the disease in the mesenteric glands or the meninges. He spoke of the means by which the tubercle bacilli could pass from the general circulation of the cow to the mammary gland, and so infect the milk. From 6½ to 10 per cent. of the fatal cases of tuberculosis were the result of bovine infection, and this form showed a predilection for lymphatic glands. He concluded by an appeal to continue the campaign against tuberculosis, urging his hearers not to allow this matter to be brought within the ambit of the present desire for financial economy.

Dr. **GERALD B. WEBB** (Colorado Springs) emphasised the family factor, and the importance of close family contact as a disseminator. In many cases a parent, before he manifested signs of the disease, had been a carrier sufficiently long to spread millions of bacilli to those in his immediate surroundings.

Experience Abroad.

Prof. F. **HARBITZ** (Christiania) spoke of the different racial incidence in the Norwegian territory. In the northern part the mortality from the disease which in 1871 was 2·2 per 1000, rose in 1901 to 4·2. In another part lupus increased from 3 to 5 per 1000. The high incidence rate among the Lapps was due to their being an inferior race.

Prof. L. T. R. **HUTCHINSON** (Bombay) said tuberculosis was very widely spread in India. In one of the divisions of the country, with a population of 20 millions the death-rate was 89 per 100,000 of the population. In rural areas it was 63, in urban areas 223, in certain towns mounting as high as 700. The figures for a few towns showed 84 per cent. of the deaths were due to the pulmonary form of the disease, 16 per cent. to other forms. He had seen very little evidence of bovine tuberculosis in that country; and the slaughter-house returns with which he was acquainted showed only one case of advanced bovine tuberculosis. In India the family factor was of very great importance. The common type of building for the very poor was the one-room tenement, which was so dark that an artificial light was required in the day-time. The whole family lived in one room, and expectoration was universal. The emigration from the villages to factory towns to work and the return to the home life at intervals was a very important factor in the rapid spread of tuberculosis in that country, and the zenana system was responsible for the greater prevalence among women.

Colonel **BUSHNELL** averred that if tuberculin were appealed to to say whether a person had the disease it gave a very dubious answer; but it gave much more reliable information if used undiluted. There were cases, however, which did not react to even pure tuberculin. In one instance 100 men in the American Army were examined with tuberculin, and, ultimately, all reacted to tuberculin, though one required as much as 20 mg. of tuberculin subcutaneously to react, which simply meant he had acquired the most effective immunisation. Generally, the fewer the cases of the disease in a community the higher the death-rate among the attacked. A question which ought to be settled as soon as possible was whether a people who did not react readily to tuberculin was likely to die quickly from the disease when they did fall victims to it. He urged that concentration should be bestowed on recent cases of the disease, giving them every care and attention, and see what happened to them in six months. More would be done towards eradicating the disease by in in four hours is only partly excreted by the kidneys, and the amount of water retained is larger when common salt is given in physiological concentration in the water. These observers concluded that there is an extra-renal delay in the transport of the salts and water. Wengraf's observations dealt with the output of all the water including the insensible perspiration, which latter was determined by repeated hourly weighings. The insensible perspiration corresponded to that of the kidneys. Breast-fed infants in general excrete in excess, whilst healthy bottle-fed infants excrete only the water (120 to 160 cm.) taken in four hours. Diuresis in breast-fed babies begins in the first hour and reaches its maximum in the second hour, while during the last two hours there is only a moderate addition to the amount excreted. In bottle-fed infants there is a steep diuretic rise usually in the second hour which reaches its maximum in three hours. The diuresis seems to be determined by the course of the hydræmia and not by the wants of the tissues. The water-excretory apparatus of a slightly dyspeptic suckling has not such control over the ingested water; the excretion curve follows the normal type, but the amount excreted is less, 30 per cent. being retained. In severe dyspeptic cases the excretion is irregular and the retention greater. In alimentary toxæmia only the insensible perspiration responds to the diuretic stimulus. The kidneys excrete no water and the retention amounts to 50 per cent., due to some renal cause. In experiments, combining common salt with the water ingested in naturally-fed children, it was found that in one-half of the cases the water taken in was excreted in four hours, in the other half 40 per cent. of the intake was retained. The urine in the former cases contained very little common salt—only 0·2 to 0·4 per cent.—a concentration greater than obtains in experiments with water alone. It is evident that the kidneys can alter the concentration. These two groups show marked variations, the one excretes the water in four hours, but retains the greater part of the sodium chloride, while the other retains both salt and water. In this latter group there is perhaps a retention of water due to extra-renal causes.

The author discusses the functional compass of the kidneys in early infancy. To determine this, experiments were made by adding common salt or urea to the food. The condition of the urine as well as the NaCl of the blood were determined. It was found that by increasing the common salt by giving one large dose of salt the percentage of salt in the blood is considerably increased, without the NaCl in the urine being in greater concentration than that in the blood. Even when large doses of urea were given, in some cases there was no corresponding urea-diuresis, and even after 24 hours the excretion of urea was not complete. Dr. Wengraf concludes that the kidneys in early infancy are capable of secreting a urine of variable concentration, but their functional compass is somewhat limited in the sense of an iso- or hyposthenuria. In the condition of hyposthenuria, in addition to an extra-renal component, there is also a renal factor. This limited functional capacity of the kidney, when the available water is diminished, as in acute dyspeptic disturbances, may play a not unimportant part in the pathology of infantile disorders of nutrition.

SHELL-FISH AND ENTERIC FEVER.

Dr. J. T. C. Nash, Medical Officer of Health for the County of Norfolk, has stated in his annual report for 1919–20 his belief that one of the main factors in the marked and continued reduction in the incidence of enteric fever in England during the present century has been the persistent warfare on "boiled" cockles from polluted layings which he initiated in the opening years of the century when medical officer of health for Southend.[1] At that time, although raw shell-fish were already under suspicion, it was thought that the boiling of cockles rendered them harmless; but he demonstrated that "boiled" cockles from polluted layings gave rise to many cases of typhoid fever, and that the so-called boiling was not real boiling, the heat employed only being sufficient to kill the cockles and open the shells. He found on cutting into "boiled" cockles riddled through a sieve that the interior contents were uncooked and barely warm, the internal temperature being below the thermal death-point of typhoid bacteria. It was a remarkable fact that from the time the "cocklers" could be prevailed upon to cease from laying the cockles in grossly polluted creeks, and, further, to sterilise them by prolonged steaming,[2] the incidence of typhoid fever fell extremely rapidly, not only in Southend, but also in London and other large towns to which the so-called "boiled" cockles were sent in large numbers. A certain number of cases of enteric fever have also been traced to the contamination of small flat fish, such as dabs, which are often caught near sewers, and being too small to be gutted, are eaten entire after cooking insufficient to sterilise the gut contents. Dr. Nash also formulated a theory that infection might be conveyed from shell-fish gathered in polluted waters to other fish on the same stall by the hands of the fishmonger. He noted several instances of infection amongst cooks under circumstances where no other member of the household contracted typhoid; in each case the cook had handled and gutted the raw fish, which other persons ate after it had been boiled or fried in oil or grease. Although emphasising the rarity of such means of infection, he believed that this was undoubtedly one way by which not only typhoid but cholera and other allied diseases were spread.[3] Their diminished incidence affords satisfactory evidence of the safeguarding of a popular foodstuff.

ARTERIAL HYPERTENSION AND CHRONIC NEPHRITIS.

ARTERIAL hypertension is a manifestation of chronic nephritis, and at the same time persistent hypertension may occur without the presence or subsequent development of chronic nephritis. This fact has been recognised clinically by the adoption of the term hyperpiesia, a term introduced by Sir Clifford Allbutt for those cases of maintained high blood pressure in which there is no evidence of kidney disease. Clinical evidence of kidney disease is not always easy to obtain in the earlier stages of chronic nephritis, and it is sometimes absent during irregular intervals in the later course of this disease. In recent years clinical evidence has been supplemented by certain functional tests of renal efficiency, and also by the micro-chemical examination of the blood. It has been shown by a number of workers, particularly in France, America, and in this country, that a retention of sugar and non-protein nitrogen occurs in many cases of severe nephritis, and in some forms of kidney disease an increase of non-protein nitrogen in the blood may be apparent at a relatively early stage. It would appear that uric acid retention makes its appearance before urea retention, while creatinine retention does not occur until the later stages of the disease. It might be expected that the application of these methods of blood examination to cases of arterial hypertension would throw a sure light on the question of coincident nephritis, but unfortunately other conditions than kidney disease lead to uric acid and urea retention in the blood. Heart failure with passive congestion in the kidneys is the most important cause of urea retention that is not due to nephritis, while gout is a cause of uric acid retention though it is uncertain as yet how far the commonly associated nephritis is here responsible for the increase of uric acid in this disease. J. Lisle Williams[4] has recently reported his results from the examination the doctor was important, too, as leader or adviser of the general public on these matters, and particularly hygiene. The bad effect of syphilis in reducing the resistance to tuberculosis could not be too much emphasised, and fuller statistics on this point must be very useful. Alcohol likewise favoured the onset of the disease, and prohibition of alcohol would greatly diminish the death-rate and the incidence rate of tuberculosis. Lastly, he counselled active propaganda work among the public, without whose aid very material progress was not to be expected.

State Action in Preventing the Disease.

Sir **GEORGE NEWMAN** said the magnitude and character of the tuberculosis problem was such that it affected not the sick man only, but the well-being of the nation as a whole. Tuberculosis cut off human life in its adolescence and adult prime, and before death there was an average of three years of sickness and incapacitation, and it was responsible for a large body of pauperism. Its ravages were worst among the poor and in congested areas. He emphasised the hygienic factors. There was need for coördination by the State in the anti-tuberculosis campaign; for without this sporadic efforts were without their due effect. Especially did the State need to see that the public were educated on the question, and this instruction should begin early in life. This intervention by the State must be both central and local, and nothing must be left to chance; all the verities of science must be utilised in the campaign, but there must be willing coöperation on the part of the people. In 1847 there died from phthisis (excluding miliary tuberculosis) 3189 persons per million of the living. In 1872 it had fallen to 1356, and in 1913 to 916. In 1920 there was a further fall to 842 per million, a reduction on the 1847 figure of 74 per cent. In that period there had been great progress in both sanitary reform and the education of the people in health matters. Together these pointed the way to future conquests. It was a great fallacy to believe that such a protean disease could be conquered by any single method. He spoke very highly of Mr. Lloyd George's National Health Insurance Act of 1911, which he regarded as one of the most epoch-making Acts ever passed by any Government. He mentioned with approval, too, the housing and public health and factory legislation; also those concerning measles, influenza, and lobar pneumonia and child welfare. And Governments could do very much in the prevention of tuberculosis by the hygienic control of food and drink, especially by restricting the excessive consumption of alcoholic beverages. He had no doubt that sobriety in a nation tended to engender a non-tuberculous people. There was particular need to attack this problem at its source—i.e., the patient's home—and he referred to the President's effort in Edinburgh in 1887, and the Departmental Committee of 1912, under the chairmanship of Viscount Astor. Sanatorium benefit came into force in July, 1912. Notification of the disease was now an established measure in most countries, also prohibition of spitting in public places, and many nations were carrying on propaganda work. The Departmental Committee to which Sir George Newman had referred, said the tuberculosis dispensary should serve as (1) receiving house and centre for diagnosis; (2) clearing house and centre of observation; (3) centre for curative treatment; (4) centre for the examination of contacts; (5) centre for "after-care"; (6) information bureau and education centre. One dispensary was suggested for every 150,000 of the population in urban areas, and the Committee laid stress on the importance in the success of such that they should have the hearty coöperation of general practitioners, who had intimate personal relations with patients and much influence in the homes of the people, forces which were very valuable in this campaign. Wherever research work had been pursued, the crucial issue of immunisation remained the supreme objective. In conclusion, he said that only by surveying this complex problem in the spirit of preventive medicine, and coördinating the respective factors concerned, and finding the hidden secrets of immunisation, would the disease at last be conquered.

The Responsibility of the Practitioner.

Prof. C. E. A. **WINSLOW** (Yale) said that in America only 25 per cent. of the cases were cured in the sanatoriums; but the average practitioner, especially in country districts, was not always a successful diagnostician. There was need for expert consultants to act in conjuction with private physicians.

Dr. **CAWADIA** (Athens) urged that medical men, not political authorities, should have questions of this sort under control, that the medical services needed control, and that special courses on tuberculosis should be given at the universities.

Dr. **RIST** said the first duty of the practitioner of medicine was to be a good diagnostician. The need for that was seriously felt in the war, when large numbers of men wrongly said to be tuberculous were sent to the base or to their own homes, when the need of men in the fighting areas was urgent. He referred with satisfaction to the inquiry by the London County Council, who found that 75 per cent. of so-called cases of tuberculosis had not that disease at all.

Colonel **BUSHNELL** agreed that the mass of medical men must be interested in this subject. He feared there was a decline of keenness in making physical diagnoses, and that the medical student wished to specialise too soon. More attention ought to be devoted to the normal chest, and the recognition of early tuberculosis should not be relegated to the expert.

Dr. **ANTONIO ESPINA Y CAPO** (Spain) said the social work in this crusade should include medical participation in the drawing up of an international anti-tuberculosis law, measures of prophylaxis directed against germ-carriers, a study of the married state in this relation, and international forms of notification.

Prof. G. E. **GASK** (London) considered that the medical profession as a whole had failed in its duties in regard to the prevention of tuberculosis. It was known that it was a preventable disease, and how it could be prevented, but doctors were not by any means sufficiently insisting on all possible occasions that the necessary steps should be taken. His own view was that ten times as much as at present could be done.

Dr. M. **JAQUEROD** (Leysin) spoke specially of the danger of promiscuous spitting, and the need for a more enlightened hygiene.

Prof. **HARBITZ** pleaded for exact information concerning the use of tuberculin and its results, and that the profession should suggest laws aimed at preventing the spread of the disease, and bringing a general knowledge on the laws of hygiene into the people's homes.

Dr. C. L. **MINOR** (Asheville, N.C.) advocated a more thorough and intimate study of the disease in medical schools, enabling clear and practical conclusions to be drawn. Doctors should be ready and prepared to apply the *verified* new discoveries.

Prof. J. C. **MEAKINS** (Canada) also emphasised the function of the general practitioner in this work, and urged a careful study of the effects of fatigue and general conditions on the sensitiveness of the individual to tuberculin, and therefore to the disease. He did not think the present-day eight hours leisure was utilised sufficiently for recreation: too large a proportion of it was given to the cinema.

Beginning with the Baby.

Dr. **ERIC PRITCHARD** said that in order to get a population resistant to tubercle, the baby should be commenced with. During the last ten years he had been trying to secure immunity in children who otherwise must inevitably have been contaminated, and of 30 children so treated there had so far been no deaths. If a child was born of a tuberculous mother he did his best to get the mother to nurse the

SECOND CONFERENCE OF THE INTERNATIONAL UNION AGAINST TUBERCULOSIS.

On the initiative of the National Association for the Prevention of Tuberculosis, a large and representative gathering assembled at the Second International Congress, held in the large hall of the Institution of Civil Engineers, Westminster, on July 26th, 27th, and 28th, under the presidency of Sir Robert Philip. Delegates were present from 39 countries, including France, the United States, Japan, Sweden, Denmark, China, Australia, New Zealand, Canada, Finland, Poland, South Africa, Switzerland, and Czecko-Slovakia. Lord Curzon and Sir Alfred Mond welcomed the delegates on behalf of His Majesty's Government.

Tuesday, July 26th.

Official Welcome.

Lord Curzon said it had been shown that where tuberculosis could be scientifically assailed it could be systematically defeated. The coördination of all the present sporadic efforts at dealing with the scourge was a condition essential to success on a large scale. Much might still be expected from the prosecution of scientific research. Lastly, it was imperative to conduct a vigorous educational propaganda among the people.

Sir Alfred Mond epitomised the steps taken in this country to combat tuberculosis in recent years. The national scheme for prevention and treatment of tuberculosis inaugurated in 1912 provided for sanatorium benefit for insured sufferers, including domiciliary and institutional treatment. This represented the beginning of a great national effort to deal with a disease, to which, owing to our peculiar climate, we seemed especially liable. Since the armistice progress in the campaign had been resumed. We had three main elements in the scheme of institutional treatment: (1) the tuberculosis officer, (2) the dispensary, (3) the sanatorium, which was intended for residential accommodation. There were 341 tuberculosis officers, 412 tuberculosis dispensaries, and 18,050 beds for tuberculous patients, an increase in the last two years of 4000 beds. There were now in progress additional buildings which would provide 3500 more beds in the next two years. The question of the ultimate value of the sanatorium was still a discussable one among experts. Five hundred places were being provided by the Government at selected sanatoriums for the training of ex-Service men. A village settlement was in course of development at Tetworth, in Cambridgeshire, where a certain number of patients would be able to take up their residence with their families, and 20 men were already in occupation. At Preston Hall, Kent, a similar effort would be made. The idea was to put and keep these men in such surroundings as would safeguard against a relapse, or a reinfection of the disease. Probably in every country the aftermath of war would keep purse-strings tight, but it was satisfactory to note the striking progress made since 1914. In 1914 there were 90,000 notified cases of tuberculosis and 50,000 deaths. In the following year 90,000 cases were notified and 54,000 deaths; but 1919 showed a reduction to 77,000 cases and 46,000 deaths, the corresponding figures for 1920 being 73,000 and 42,000. Bearing in mind the interruption brought about by the war, those figures were very striking.

Short speeches promising support to the crusade in their respective countries followed from 20 delegates, mostly delivered in excellent English.

Senator André Honnorat, representing France, read a contribution, in French, in which he said that, next to the war, tuberculosis proved the most drastic decimating agency among the young men of his country. He outlined the measures already taken and in contemplation for combating the disease.

Fundamentals of Pathology.

Colonel G. E. Bushnell (U.S.M.C.) submitted a paper containing a general review of the subject. Both diagnosis and the measures to be adopted depended on a correct interpretation of the disease processes at work. At present, despite all the advances which had been made, there was still lacking a general agreement as to fundamentals in regard to the pathology. Tuberculosis was pre-eminently an insidious disease, and as in most disease conditions, treatment was most hopeful in the early stages, hence the von Pirquet reaction ranked, in his opinion, second in importance only to Koch's discovery of the bacillus. Tuberculous infection was not necessarily identical with tuberculous disease. Very few people escaped the invasion of so widespread a contamination, but only a proportion failed to throw it off—i.e., they did not manifest the disease. Physical diagnosis gave the key to infection which had overcome the body resistance. The lesion found in the tuberculous patient was seldom his initial lesion. We did not yet know how far tuberculisation of the race was accompanied by lung lesions; 86,000 French soldiers fell victims to tuberculosis while under military service. There must, he contended, be a closer study of the nature of the thickening often found in the upper lobes of the lungs. Epidemiological questions could only be solved by a long process of research, and this the physician could not be expected to undertake unaided. Especially should investigation be made among people who were apparently well. Tuberculosis alone among common diseases received but scant consideration at the hands of most of the population, and in many cases even inflammatory reactions passed unnoticed. Some people, however much exposed to the disease and however bad the conditions they lived in, did not get the disease. The difference was not due to bad air, or bad food, or bad hygiene, or overwork, or race or climate. To say it was a matter of predisposition was only to confess our ignorance. The study of this disease should be prolonged beyond the period usual with investigators, and beyond what was possible to any single body. It must be in the hands of a governing body which could initiate a universal campaign, which should have no limitations, and should have the power to loosen the purse-strings. In other words, there must be coöperative activity in combating this disease, but every effort should be made to come to an agreement on fundamentals.

Sir Arthur Stanley intimated that the Prince of Wales had signified his acceptance of the post of President of the National Council for the Prevention of Tuberculosis, rendered vacant by the death of Lord Balfour of Burleigh.

On Tuesday afternoon the business meeting of the National Council was held. Sir Arthur Stanley occupied the chair, and in a short speech said he felt that in this campaign they were on the winning side.

The "Œuvre Grancher" System.

Dr. P. F. Armand-Delille (Paris) read a paper on this system, which had now been in operation 17 years. The gravity of infection by tubercle depended on the dosage of bacilli received. If a guinea-pig received 10 tubercle bacilli at a time it developed the disease, but not if there were only 2 or 3. A child might have a slight tuberculous contamination from the dust of cities and present a positive von Pirquet, but might not develop tuberculous lesions; but if kept in close proximity to a tuberculous parent was found to have a primary ganglionic focus of the disease. The Grancher system consisted in placing out in healthy rural families children whose lives were in jeopardy through living with tuberculous members of the family. The children must previously have been vaccinated against small-pox, and be free from adenoids. Of 2300 children of Paris so placed, only 7 developed tuberculosis, and there were 2 deaths from meningitis three weeks after being transferred. This meant practically the extermination of the disease among children. There were now more than not been included in this Act, but will appear in the proposed reform of the medical curriculum. The title of "Arzt" (equivalent to doctor) will be protected by law and will be applicable only to persons qualified as above. The practitioner will not be permitted to have more than one office, nor may he practise or dispense medicine concurrently in several places. The doctor will not be allowed to follow an accessory occupation inconsistent with the dignity of the profession. His duties towards patients are defined in a series of regulations, amongst which the following are important. The doctor must use all his knowledge and conscience, according to the latest acknowledged achievements of his profession, in the treatment of those entrusted to his care. In urgent cases he is bound to give aid, and a refusal to act may bring him into conflict with the law, unless there are obvious reasons—e.g., personal disability—for his refusal. The doctor may claim compensation for first aid from the local authorities, but is entitled to refuse to treat the patient regularly unless the latter is in danger, and unless the disease is urgent. Professional secrecy is not as absolute as might be deemed wise in the new Act, for it is stated that every doctor is bound to treat as secret all disclosures by his patients made known to him during the course of or pertaining to the illness "unless higher interests intervene." This ruling will, no doubt, encounter severe opposition, as we have hitherto been used to maintenance of absolute secrecy. In future, moreover, the doctor giving an incorrect testimonial "to oblige a patient," as is sometimes done, will be punishable by severe fines. The Medical Council, or representative body of the medical profession, which has hitherto had little or no means of imposing a sentence passed on an accused member of the profession, will in future be entitled to impose a fine up to 10,000 kronen, or, if deemed necessary, to strike the name of the culprit off the medical register permanently or for a certain period. The Medical Council will, however, be required to apply the methods of regular law courts in dealing with an offence demanding such a strict punishment. The further details of the new Act are not very different from those now in force, but the profession will strive for the embodiment of all its demands for a modern perception of its rights and duties.

Protection of the Title of Specialist.

Some time ago the Vienna medical organisation undertook the disagreeable task of defining for limited use the term "specialist." A committee consisting of representatives of all medical corporations, universities, and hospitals evolved a scheme, the propositions of which Prof. Strausky has set out as follows. Only fully qualified doctors of medicine, having special training beyond the general instruction of medical men, should be entitled to call themselves specialists. At present only the following specialties are recognised: internal medicine, surgery and orthopædics, pædiatrics, neurology and mental diseases, ophthalmology, rhino-laryngology, otology, dermatology, venereal diseases, gynæcology and obstetrics, electro-pathology and radiology, and dentistry. Doctors should not be permitted to specialise in more than one branch of the above specialties, except in those which are naturally allied—e.g., otorhino-laryngology, mental and nervous diseases, &c. The title of specialist should be protected by law, equally with the degree of M.D., and should be granted by a special body or commission, consisting of members appointed by Government, the medical organisation, and the Medical Council. The applicant for the title would have to prove before this body that he has worked for a period of not less than two years in operative specialties, not less than three years in a special ward or clinic as assistant to the chief, or for four years if only as a member of the staff of such a ward or clinic. An examination of the candidate in the theory and practice of his selected specialty will be held. All professors of universities and others already recognised as specialists by the fact of their present occupation of posts as heads of special departments or as teachers (privat-docents) are exempt from such examination, and doctors who have already practised as specialists for at least two years would also be exempt. Furthermore, doctors who had graduated at least four years before taking up a special branch would be eligible for the title of specialist on binding themselves not to take up general practice. These regulations, it is thought, will meet the just demands of both general practitioners and specialists, and should regulate in an amicable way the relations between these distinct parts of the profession. The propositions contained in Prof. Strausky's report are being submitted to the profession for judgment, and if approved will soon be brought into force.

Bathing Fatalities.

The great heat has tempted large numbers of people to bathe in lakes and ponds, as well as in the open river; the negligence of bathers, together with the complete absence of first-aid arrangements, has resulted in many cases of drowning. The Medical Society of Vienna has therefore published in the daily papers a short instructive article warning those with affected hearts, and especially those with diseased ears, against the danger of cold water. The latter category of persons are especially unaware of the risk they run; a perforation in the drum may easily cause labyrinthine irritation and vertigo. The principles of artificial breathing and the methods of resuscitating the apparently drowned are also described, and public authorities are urged to establish a regular life-boat service, or at least to keep ready for use a small boat on all water used for bathing purposes. The teaching of swimming for school children is earnestly recommended as one of the chief means for doing away with these fatal accidents. In addition to the instructions and warning pertaining to the bathing itself, the public are also warned against the disagreeable—not to say dangerous—effects of over-indulgence in ice-cold drinks and fruit as well as of alcoholic beverages before bathing. Whether because of these warnings or not the number of drowning fatalities has recently been considerably diminished.

July 20th.

Public Health Services.

The London County Council and Public Health during the Heat Wave.

REPLYING to Mr. J. D. Gilbert, M.P., who asked for information as to public health in London during the recent dry weather, especially as to possible increase in scarlet fever or other epidemics, Captain Warburg (Chairman of the Public Health Committee of the L.C.C.) said the weekly average number of cases of scarlet fever had dropped from 925 in October, 1920, to 435 in April last. Since April the number of notified cases had been gradually rising, the present weekly average being 611. Diphtheria had decreased since the autumn of last year. With regard to other epidemic diseases, the position had on the whole been very satisfactory. The hot, dry weather did not appear to have affected, to any noticeable extent, the general health of the people, except that there were more persons, especially children, affected by slight febrile attacks, accompanied in some cases by catarrh of the respiratory passages. There had also been a slight increase in the number of deaths among children under two years from epidemic diarrhœa. It had not been found necessary to take any special action in the direction of safeguarding the health of the community apart from the measures of prevention which are ordinarily adopted.

Welfare of the Blind.

The General Purposes Committee of the L.C.C. has investigated the question of the establishment of a scheme for the welfare of the blind in the County of attention directed to the children in this way than bestowing energy on tuberculosis dispensaries for established cases.

The discussion was continued into the afternoon.

Sir **GEORGE MCCRAE** (Scottish Board of Health) spoke of the work done in Scotland in this respect, referring to the farm colony established by the President (Sir Robert Philip), and to the fact that when the National Insurance Act became law, Scotland had all the machinery ready, and 60 per cent. of the local authorities had adopted notification of the disease. In that country to-day there were 101 sanatoriums and other institutions, comprising 3232 beds actually in use, apart from accommodation for other diseases. The deaths from the disease of all forms in the country were in 1919 6326, as against 8517 in 1910. In Scotland they recognised the great importance of housing in this matter, for bad houses were the greatest barrier to progress, and the housing in that country was deplorable.

Further Discussion of Ætiological Factors.

Prof. **S. LYLE CUMMINS**, representing Great Britain, paid a warm tribute to the great work done in connexion with this combat by the French, and said the contribution just delivered to the Conference by Prof. Calmette was one he did not expect to hear surpassed. When tuberculosis attacked a fresh people it conformed to all the behaviour of an acute infectious disease, but not among victims in a people already subject to it. He spoke of the lessons in this regard afforded by the disease among the various constituent peoples taking part in the war. It supplied the reason why our army supplied a long pension list instead of a high death-rate from the disease; and he put in a plea on behalf of the ex-soldier the true nature of whose disease was not early recognised, but who was eventually found to have tuberculosis.

Dr. **J. H. LANDIS** (Cincinnati) contended that the discussion had served to confirm the impression that the ætiology of tuberculosis was the part of the subject about which least was known. Some contended that at whatever age the disease might manifest itself it was the outcome of an infection acquired quite early in life, and that infection late in life seldom occurred. But the speaker considered that adult infection took place oftener than was usually thought. In the United States the black race showed double the death-rate of that of the white people.

Dr. **L. G. HAYDON** (Pretoria) spoke of the great influence in the spread of tubercle exerted detrimentally by the incursion of kraal village inhabitants (constituting the mass) to centres of industry where they came into contact with infected civilised people, and their periodic return to their homes. These cases he agreed were rapidly progressive and fatal, and the direct means of spread was by expectoration, aided, he did not doubt, by Indian hemp smoking.

Dr. **H. SUTHERLAND** (Ministry of Pensions) outlined the policy of the Ministry in regard to tuberculous ex-soldiers, and those who were subsequently found to have that disease.

Dr. **W. CAMAC WILKINSON** (London) referred to work in Australia in connexion with this disease, and averred his belief in the efficacy of tuberculin. He emphasised his view that generalisations about the pathology of the disease should be founded on nothing less than post-mortem examination. The von Pirquet method was unreliable for diagnosis, as it was too sensitive; there should be subcutaneous injection of tuberculin, and if that was positive it was proof of the presence in the body of living active tubercle bacilli.

Dr. **CH. RIST** (Paris) said that if a child having consumptive parents was removed from them in early life and brought up in non-infectious surroundings, he would not only not be likely to develop the disease, but the incidence rate among such would be lower than among the general population. The high susceptibility of certain races was due to the disease not having been experienced in childhood; this received ample emphasis in the war in the case of black contingents. He believed hereditary predisposition played some part in the production of the disease, but not to the extent usually supposed. He combated the idea that physical robustness necessarily meant good resistance to tubercle; and he instanced a family which lived in ideal conditions and a hygienic life, but the children of which died rapidly of tubercle. Also it was clear that the Irish were more, and the Italians less, susceptible to the disease than the commonality of people. He agreed with those who denied to the von Pirquet reaction a practical diagnostic value. If that fact were generally recognised it would save much disappointment.

Dr. **H. HYSLOP THOMSON** (M.O.H. Hertford) spoke of the prevalence of tuberculosis among the mentally-defective and feeble-minded. In a large institution with which he was connected, the death-rate from the disease in 1914 was 20 per 1000, and during the war that figure rose to 118. The clinical manifestations of the disease among these patients differed markedly from those in ordinary folk in the fact that there was no cough and no sputum and the chief lesions were intestinal. There was a field here for an instructive investigation.

THURSDAY, JULY 28TH.

The Rôle of the Medical Profession in the Prevention of Tuberculosis.

The last open session of the Conference was devoted to this aspect of the subject, and was remarkable for two important contributions, from Sir Humphry Rolleston and Sir George Newman, which were followed by a good discussion.

Sir **HUMPHRY ROLLESTON** said the isolation of all carriers of the bacilli would be effective only if adopted in the stage before the discharge of such bacilli from the individual. If all latent cases were detectable by the von Pirquet test, 90 per cent. to 95 per cent. of urban populations and an enormous number of cattle would prove to be infected. Krause had said that tuberculosis was the price we paid for our civilisation. The Tuberculosis Order of 1912–13 should be revived as soon as possible; this was asked by the National Council for the Prevention of Tuberculosis at its meeting last year. Small doses of the infection in early life probably conferred some degree of immunity; the danger lay in mass infections. Periodic examination of children every six months by the method of Calmette would be of great service in detecting the onset of infection. The test should be applied to a selected area without delay. The question of general hygiene could not be separated from this campaign; improved sanitary and physiological conditions, proper housing, good feeding, healthy and not excessive work, suppression of alcoholism and venereal infection were essential for the prevention of diseases, of which tuberculosis was the commonest. Medical men were in a position to diminish and prevent infection, to improve the resistance of the people by securing healthy surroundings, proper feeding and occupation, and to promote the education of the masses in matters of hygiene. The doctor could take part in the prevention of the disease by teaching students and by helping on research. He constituted the first line of defence against all diseases; he was acquainted with the life-history and physical condition of the members of the families who came under his care, and he had an unequalled opportunity of educating them in the laws of physiological righteousness. This was the more important as patients did not usually seek advice until disease had become definitely established. Teachers in medical schools had a great responsibility in forming the outlook of the future general practitioner in regard to this disease. But few medical schools in this country gave a systematic course of instruction in tuberculosis, in which early diagnosis should receive special emphasis. There was also need for the creation of University chairs in Tuberculosis, such as those in Edinburgh and Wales. And

"Audi alteram partem."

AN APPEAL FROM THE RUSSIAN RED CROSS.

To the Editor of THE LANCET.

SIR,—I appeal to all my colleagues in the British Isles and the British Empire, imploring them to hear the cries and groans of the millions of my countrymen who are dying from starvation, cholera, typhus, dysentery, and malaria. The women and children are waiting for your help; not merely your sympathy, but your real and material help. We, who are physicians, know that to infectious disease there are no boundaries, no nationality, no rich, no poor, no strong, no weak. Infectious disease, in its march, destroys all that it meets.

I ask all British physicians to raise aloft the banner of humanity for speedy help to my country, by sending Medical Sanitary Detachments, Medicaments, and Hospitals to the areas of distress and famine. I shall be happy to furnish all particulars on application.

I am, Sir, yours faithfully,
B. BELILOVSKY, M.D. Petrograd,
L.R.C.P. & S. Edin. and Glasg.

S, Eccleston-street, London, S.W. 1.
(Telephone: Victoria, 2541.)

ROSACEA.

To the Editor of THE LANCET.

SIR,—Dr. A. Whitfield's Lumleian lectures, which you have recently published, are models of their kind, and in my opinion are among the most important contributions to the scientific study of dermatology that have appeared in this or any other country for many years. I have read them not once, but several times, and each time with more and more enjoyment. But I should like, if I may, to join issue with him on one point, namely—the ætiology of rosacea, and his classification of patients with this condition into two types: "the irritative and the toxic." I think he has to some extent misinterpreted some of my remarks in the paper on gastric analysis in cases of rosacea, which I published some time ago with Dr. J. A. Ryle, and I therefore wish to recapitulate the views which I then attempted to put forward.

Everything points to the idea that in rosacea the flushing of the face depends on some abnormality of the gastric mucous membrane. Probably in the majority of cases, if not in all, there is actual chronic gastritis—i.e., inflammation of the mucous membrane—and, although irritants such as alcohol, tea, coffee, condiments, &c., may be direct or predisposing causes, in many cases the constant swallowing of pus from the mouth or nasopharynx would seem to be the most important factor in producing the gastritis. The presence or absence of inflammation, however, in the gastric mucosa is difficult to determine, owing to the rapid post-mortem changes that normally take place in it. In early cases of rosacea the secretion of hydrochloric acid by the stomach may be normal or even temporarily excessive; in chronic cases there is almost constantly either marked hypochlorhydria, or frequently complete absence of free acid.

With regard to Dr. Whitfield's two types—the irritative or angeioneurotic and the toxic—although the distinction is a useful one clinically, I think that the flushing is in both cases dependent on the condition of the gastric mucous membrane. It can easily be understood that in persons with an unstable vasomotor system—and such are usually, though by no means always, women—the irritability of the gastric mucous membrane resulting from gastritis is apt to make the flushing of the face a more marked and frequent symptom than it is in their more phlegmatic fellow-sufferers. In the toxic type, although oral and nasopharyngeal sepsis and the secondary intestinal infection resulting therefrom may lead to severe toxæmia with "a pale, lemon-tinted complexion," and may predispose to staphylococcal infection of the skin, the rosaceous flushing is probably still dependent on the gastritis set up by the swallowing of pus. In my experience the toxic acne of middle-age, to which Dr. Whitfield refers, is usually accompanied by some degree of rosacea, and probably depends on the lowered resistance to infection that chronic sepsis creates.

Dr. Whitfield says that he cannot agree with my description of the appearance of the tongue in rosaceous patients. I admit that it is not a constant feature, but the majority of cases of both types certainly do have the pale, smooth (i.e., the papillæ are hardly apparent), flabby tongue that I described; it is often clean, though, of course, in the toxic type it is dirty and furred.

In conclusion, I will describe one case which illustrates some of the points I have raised:—

The patient is an unmarried lady, who came to see me first in April of this year for flushing of the face and pustules on the chin, to which she had been subject for the past five or six years. She had long suffered periodically from sore throats and laryngitis, and she complained of chronic post-nasal catarrh. Four years previously she developed "goitre," after an attack of tonsillitis, and, although this disappeared after a time, the thyroid continued to enlarge from time to time. She belongs certainly to the angeioneurotic type, and flushes very easily. When I first saw her she had mild persistent rosacea with pustules on the chin, but she was not anæmic and her complexion, apart from the pustules, was good. Her tongue was smooth, very pale, and slightly indented at the edges; her teeth were in good condition, but her tonsils were very septic, and contained definite pus in their crypts; muco-pus could also be seen in the nasopharynx. Although I could not arrange for a test-meal, I ordered her dilute hydrochloric acid in 40 minim doses after meals, and a resorcin-calamine lotion. She returned to see me a few days ago, saying that as long as she took the acid she remained entirely free from pustules, but whenever she omitted to do so for a few days a fresh crop would invariably appear. She no longer flushes after meals, but does so when excited or nervous; the flushing, however, on these occasions is not confined to the rosaceous areas.

Here, I think, we are dealing with an example of the angeioneurotic type, in whom gastritis had been produced by the constant swallowing of pus from septic tonsils and the nasopharynx. Although the enlargement of the thyroid, and, perhaps, indirectly the vasomotor instability, were probably due to the throat infection, the patient can in no sense be considered to belong to Dr. Whitfield's toxic group.

I am, Sir, yours faithfully,
H. W. BARBER.

Devonshire-place, W., July 30th, 1921.

THE SUPPOSED EXTERNAL EFFECTS OF HUMAN VISION.

To the Editor of THE LANCET.

SIR,—With reference to the paper by Dr. C. Russ in THE LANCET of July 30th, I would like to point out that, as such discoveries as these are as good as drink to the mystic and charlatan, it would be as well if they could be thoroughly investigated without loss of time. Indeed, their importance as error might well exceed their interest should they turn out well-founded, great as that must be for psychology as for physics. While acknowledging the restraint of Dr. Russ in his conclusions and disclaiming any right to criticise his method or observations, there appear to be certain considerations and questions with which he has not dealt. "The fact that the direct gaze or vision of one person soon becomes intolerable to another," which was the starting point of his research, is (in my opinion, adequately) accounted for already. The discomfort is not sensory but arises in the sphere of ideas and sentiments, and is manifestly dependent upon the past history of the patient and his psychic relations with the gazer. Thus a woman may feel child, because he thought this imparted some passive immunity. At the earliest opportunity he gave a diagnostic injection of Koch's old tuberculin. If there was a reaction, he concluded that the child had already been tuberculised by the mother, and he continued with increasing doses until he got to a dose of a milligram. This required five months, and during that time the child went on well. If the mother had open tuberculosis the infant became tuberculised soon after birth. He advocated the systematic sending of such children to tuberculosis dispensaries, where they could have the kind of treatment he had carried out.

The **President** expressed his appreciation of the help being given by the Press, and Dr. **Minor** voiced the gratitude of the delegates from abroad for the kindly reception and entertainment accorded them.

The Conference then closed.

During Friday visits were paid to a number of sanatoriums and hospitals, and on Tuesday international delegates were entertained at luncheon by the Government.

TREATMENT AND EDUCATION OF PHYSICALLY DEFECTIVE CHILDREN:

CONFERENCE AT NEWCASTLE-ON-TYNE.

A Joint Conference arranged by the Newcastle Invalid Children's Aid Association and the Central Committee for the Care of Cripples was held at the Royal Victoria Infirmary, Newcastle-on-Tyne, on July 19th. Both morning and afternoon meetings were well attended. Lady **Parsons** took the chair at the morning session, which was first addressed by Prof. **Rutherford Morison**, who, in opening, estimated that there exist three cripples for every 1000 of the population, and that at this rate there are 1500 cripples in Newcastle and Gateshead. Of this crippling 40 per cent. is due to tuberculosis and 26 per cent. to infantile paralysis. Prof. Morison emphasised the importance of prevention, instancing what has been done in other diseases, and claimed that with preventive measures and adequate early treatment three-quarters of the crippling could be prevented. He also called attention to the psychology of the cripple, how he is apt to be singled out by the healthy boy or girl as a subject for persecution and contempt, and how this and his difficulties in the struggle of life are apt to sour him and to make him morose. Prof. Morison mentioned the existence of a home for crippled children in Gosforth, associated with the name of Mr. Sanderson. This, until lately, had been a home and a school, but no surgical treatment had been carried out; lately, however, arrangements have been made for operative treatment to be carried out at another institution, and it is hoped to make the home a centre for both education and treatment of cripples.

Mr. R. C. **Elmslie** related his experience of the progress that has been made in the surgical and educational care of crippled children in London during the last 12 years; better coöperation between the schools and hospitals and increased provision for tuberculous children had resulted in much improvement in the condition of the children, but much still remained to be done, more particularly for children with infantile paralysis. Surgeons are still obliged to do a great deal of work in the out-patient department that can only be really efficiently carried out if the children are in an institution. Speaking of the education of cripples, Mr. Elmslie pointed out that every cripple must eventually compete in the labour market with healthy rivals, and unless he has been educated and taught a trade his position is hopeless. In his opinion no institution has any right to keep in crippled children for prolonged surgical or other treatment without arranging for their education, nor to keep them in and educate and clothe them without arranging for adequate treatment.

Mr. H. **Platt**, relating experiences from visits to America, pointed out that the chief difference in that country is due to the much larger number of American surgeons who have relinquished other branches of surgery in order to devote themselves to orthopædics. In most of the medical schools and universities in America there is a chair of orthopædics, and there are far more hospital beds given up to the work than there are in this country.

Afternoon Session.

In the afternoon, under the chairmanship of Sir **Theodore Morison**, Mr. **John Fraser** was the principal speaker. Mr. Fraser devoted himself chiefly to the prevention of tuberculosis, pointing out that attention to a few simple measures might do much. The measures advocated were: (1) Preventing a child during early years from coming into contact with persons suffering from open tuberculosis; (2) attention to the hygiene of the child's mouth and throat; (3) boiling milk; (4) special care of a child after an attack of measles, whooping cough, &c., when there is an undoubted increased liability to tuberculous infection.

After an active discussion the following resolutions were unanimously adopted:—

1. That this Conference is of opinion that a local branch of the Invalid Children's Aid Association should be formed with the following objects: (1) The procuring of all available means of assistance, care, and education; (2) the keeping of records; (3) the discovery of early cases of crippling disease.
2. That hospital school accommodation is most urgently needed now, and should be provided at the earliest possible date.

VIENNA.

(From our own Correspondent.)

Deaths of Eminent Physicians.

Within the last few weeks the medical faculty of the Vienna University has sustained the loss of several of its most esteemed members, who were responsible to a great degree for the high position held by Vienna in the scientific world. Amongst the best known was Prof. V. von Urbantschitsch,[1] the successor of Politzer as head of the otological clinic. Although in no way as eminent as his predecessor, he was an excellent teacher; to his efforts are due the recognition and treatment of deafness as a social disease. He was the instigator of the Union "Vox," which endeavours to unite the deaf and to alleviate their condition by promoting instruction in lip-reading and testing all apparatus designed as an aid to hearing. As a result of the war the number of deaf persons has largely increased; many of them owe a great debt of gratitude to Urbantschitsch for the help obtained through his initiative. He carried out original research concerning the physiology of the ear and its correlations to the other senses—vision, taste, and smell. A few days before him there died Prof. Viktor Lang, the President of the Vienna Academy of Sciences, a famous physicist, the teacher of numerous generations of students in medical and general physics. He was an authority on crystallography and the physics of minerals; early in his career he gave up medical practice and devoted himself to science, but retained a great interest in all sides of medicine.

A New Medical Act.

As a result of the medical strike effected some few weeks ago the Government has now fulfilled its promise and brought before the National Assembly a Medical Act of which the following are the leading points. In future no person may practise medicine in Austria unless he or she can produce a diploma of Doctor of Medicine, granted or confirmed by an Austrian medical faculty. The preparatory hospital year, as demanded by all medical corporations, has made before the completion of medical demobilisation, these appointments would now again be declared vacant and re-advertised, or whether the original appointments were to be considered the permanent appointments of the present holders.—Major TRYON (Parliamentary Secretary to the Ministry of Pensions) replied: I would refer my hon. friend to the answer given to the hon. Member for Hemsworth on June 16th, of which I am sending him a copy.

---

[1] See annotation, The Lancet, July 16th, p. 144.

Home Hospitals for Defective Children.

Lieut.-Colonel FREMANTLE asked the President of the Board of Education if, under the grant regulations of the Education Act of 1918, a grant of some £16 to £25 was made in respect of each child of the age of 2 years and upwards residing in a home hospital for physically defective children; that a certificated teacher must be employed in the training of such children, and if he was aware that in some cases certificated teachers, from £200 a year, were employed in such homes for teaching about a dozen children for a few hours a day for five days a week, despite the fact that before the Act came into force adequate teaching was given to such young children free of charge by voluntary helpers; and would he consider whether a more economical method could be employed.—Mr. FISHER replied: The grants payable to certified voluntary boarding special schools which provide maintenance and treatment as well as instruction are, under Grant Regulation No. 19, approximately as stated. The qualifications required in the teaching staff of these schools are set out in Appendix B of the Regulations, and have not been raised since the passing of the Act of 1918. Proposals for economy in the staffing of individual schools are, and will be, considered by the Board on their merits.

Ex-Service Men in Mental Hospitals.

Colonel WEDGWOOD asked the Minister of Pensions whether he had any authority to intervene in any way in the cases of ex-Service men, under the Lunacy Acts, who had the status of private patients.—Mr. MACPHERSON replied: I have no authority to intervene in matters coming within the scope of the Lunacy Acts; but in all other questions affecting Service patients I have the same powers as in the case of other pensioners. I may, however, say that by the courtesy of the Board of Control a medical officer attached to Ministry headquarters now visits, in conjunction with the Commissioners of the Board of Control, mental institutions in which ex-Service men are under treatment as private patients.

Committee on Leadless Paints.

Captain BOWYER asked the Secretary for the Home Department what was the composition and terms of reference of the fresh committee which he had promised to appoint to examine the recent further evidence as to the results obtained with leadless paints—Mr. SHORTT: I am not yet in a position to announce the composition and terms of reference of this Committee, but I hope to do so shortly.

Mentally Deficient Children.

Major BIRCHALL asked the Minister of Health whether he would state the number of Poor-law children in separate Poor-law institutions for the sick, in separate Poor-law institutions for the mentally deficient, and in non-Poor-law institutions on Jan. 1st, 1921.—Sir A. MOND replied: The numbers on Jan. 1st, 1921, were as follows:—

—	Not mentally infirm.	Mentally infirm.	Total.
In separate Poor-law institutions for the sick ..	7086	99	7185
In separate Poor-law institutions for the mentally infirm	—	1329	1329
In non-Poor-law institutions (not being lunatic asylums)	8550	*689	9239

* Including 630 in separate institutions for the mentally infirm.

THURSDAY, JULY 28TH.

Housing Conditions in Scotland.

The House went into Committee on a Vote of £1,875,999 for the salaries and expenses of the Scottish Board of Health, Mr. J. HOPE in the chair.

Mr. ROBERTSON moved to reduce the Vote by £100 for the purpose of calling attention to housing and the insanitary condition, especially of the mining towns and villages, in Scotland. He said the Housing Commission's report in 1911 stated that there were in Scotland no less than 120,730 single-apartment houses, equal to 12·8 of the total number of houses. Of the total population of Scotland 100,000 people at that date were living in single-apartment houses, and 39·3 per cent., or nearly 2,000,000, were living in two-apartment houses. The conditions were worse now than they were in 1911, because, according to the census figures, the population had increased by 2½ per cent. In no fewer than 800 houses the inmates exceeded eight in number. There were thousands of instances at the present time of more than one family living in a two-apartment house, and many instances of more than one family living in a single-apartment house. There were instances of 11 or more persons living in a single room. In 1911 the death-rate in one-roomed houses was 20·14 per 1000, in two-roomed houses 16·83 per 1000, in three-roomed houses 12·63 per 1000, in four-roomed houses 10·32 per 1000, and so on. In the county of Lanark there were many cases where consumptive patients were obliged to live in the same room with several other persons. The cruelty of it was that when these people were taken from these dens, and hope had been revived in their breasts by residence in a sanatorium, they were driven back again to live out their existence in the dens owned by rich men where they contracted the disease. Do not let them cast their eyes to the ends of the world and beat their hands on their breasts and thank God that we were not like other nations. Why were our wealth producers rotting in the slums while the Government were spending money on military adventures in far-off lands that had little connexion with our country? He sincerely hoped that on this question of housing in Scotland there would be no holding back.

Mr. MUNRO (Secretary for Scotland) said that he agreed with Mr. Robertson that the conditions of housing in some of the mining districts were an outrage upon decency and a blot upon civilisation. As regarded tuberculosis and infantile mortality, however, it was curious to find, notwithstanding the shocking housing conditions to which Mr. Robertson referred, that both infantile mortality and tuberculosis had steadily declined in Scotland during the last 10 years. While in 1911 infantile mortality in Scotland was 112 per 1000, it had diminished in 1920 to 92 per 1000; and while the death-rate from phthisis in Scotland in 1910 was 115 per 100,000, the figure had fallen to 88 in the year 1919. He claimed that, so far from having neglected the housing of the working classes, the present Government had made a larger contribution to the solution of housing problems in Scotland and England than any other Government in the history of this or any other country in Europe, or perhaps in the world. All the Government were doing was to mark time and call a halt in approving tenders until sufficient progress had been made with the houses that were now under construction.

Mr. W. GRAHAM said he was not in any way an authority on medical matters, and he did not know how far it was possible to trace the prevalence of cancer to bad or indifferent housing conditions, but a very large proportion of the cases came from the same locality, and that seemed to point to the importance of some investigation from the standpoint of this disease, which in some way appeared to be taking the place of tuberculosis.

Captain ELLIOT: Surely it is agreed that cancer occurs in good houses as well as bad.

Mr. GRAHAM said he entirely agreed that they found cancer in every grade of society, but in Scotland a very large number of cases came from certain areas, and he suggested that while tuberculosis was decreasing other diseases were increasing, and that seemed to be a matter worthy of investigation.

After further discussion the vote was agreed to by 173 votes to 58.

War Neurosis and Shell-shock.

Mr. MILLS asked the Minister of Pensions what was approximately the total number of pensioners now receiving treatment for war neurosis and other shell-shock conditions; and what was the number and proportion of these cases who had yet had no treatment or were awaiting treatment.—Mr. MACPHERSON replied: There are now approximately 3400 men under treatment in institutions for disabilities of this nature. About 900 are awaiting admission, and, if unable to work, are receiving treatment allowances. I may add that there are a large number of cases in which out-patient treatment is found to be sufficient.

Medical Courses in Psychotherapy.

Mr. FREDERICK ROBERTS asked the Minister of Pensions whether a medical man trained as a psychotherapist by the Ministry of Pensions, and refused work as a neurological specialist, would be accepted for work on the neurological boards in London in place of one of the untrained ordinary members or neurological members of such board, or whether, in the interests of the pensioner, such training was to be allowed to go to waste.—Mr. MACPHERSON replied: The scheme of training medical men in psychotherapy was instituted by my Department to meet the urgent need for this particular form of treatment, and until the demand in the different areas has been fully met, the question of employing them on medical boards does not arise.

The Price of Spirits.

Mr. HIGHAM asked the Prime Minister whether he would consider the advisability of removing the restrictions

London. On the recommendation of the Committee the Council has resolved that it will not at present provide or maintain institutions for adult blind persons, but will utilise to the greatest extent possible existing charitable and other associations. It was further agreed that a central council shall be established by the L.C.C. for advisory and other purposes, consisting of representatives of associations for the blind, representatives of the Council, and, if deemed desirable, other persons with special knowledge of the needs of the blind. A detailed welfare scheme which has been evolved by the General Purposes Committee is being forwarded to the Minister of Health for his approval.

Treatment of Tuberculosis.

In connexion with the scheme of the L.C.C. for comprehensive treatment of tuberculosis in London, the following recommendations by the Public Health Committee were adopted :—

(*a*) That the Ministry of Pensions be urged to expedite its decisions as to its acceptance of responsibility for the treatment of tuberculous ex-Service cases, not only in new cases, but also in cases at present receiving residential treatment, in which the Ministry of Pensions has not yet decided that the tuberculous condition of the patients is attributable to or aggravated by war service.

(*b*) That the Public Health Committee be authorised to arrange for the completion of courses of treatment and training in cases of ex-Service patients at present receiving treatment and training and in respect of whom the Ministry of Pensions decides that the tuberculous condition of the patients is not attributable to or aggravated by war service.

(*c*) That the Council is not prepared to include, amongst the objects of expenditure on the tuberculosis dispensary service ranking for the Council's grant under its scheme for the treatment of tuberculosis in London, expenditure by metropolitan borough councils on the provision of extra nourishment.

(*d*) That in cases in which the income of an insured person, accepted for residential treatment for tuberculosis, is the main support of the family, no assessment be made for contribution towards the cost of such treatment.

The Public Health Committee has accepted an offer by the authorities of Brompton Hospital to allocate for the sole use of the Council 260 beds at Brompton Hospital and 100 beds at Frimley Sanatorium, for lump sum payments of £4000 a month. A similar arrangement has been entered into with the Victoria Park Hospital authorities, the monthly payments in this case being £888 17*s.* 9*d.* for 80 beds. The county medical officer has been authorised to arrange for 40 observation beds to be allocated to the Council at the Royal Chest Hospital, City-road. The observation beds at Brompton Hospital will be reduced by the same number.

Doctors' Certificates.

It was reported to the Middlesex Insurance Committee recently that the Tottenham Medical Union had asked the ruling of the Ministry of Health in the following circumstances : "A" is an insured person on the panel of "X." He goes to "Y," who is a panel doctor in the same locality known as "X," and pays him for treatment privately. In the event of "A" requiring a certificate of incapacity in order to obtain his sickness benefit, should "Y" give an ordinary National Health certificate or write a private certificate?

The Minister replied that an insurance practitioner is only entitled to use the official form of certificate (Form Med. 40) for patients whom he is attending as insured persons. An insurance practitioner who is treating an insured person as a private patient would therefore have no alternative but to issue a private form of certificate.

Insured persons are not disqualified from receiving sickness benefit by obtaining medical certificates from doctors attending them in a private capacity, and a society is not entitled to refuse to receive and consider, in connexion with a claim to benefit, certificates not given under the medical certification rules. On the contrary, a society is bound to take into due consideration any medical certificate put forward in support of a claim. It is perhaps unnecessary to add, on the general question of the acceptance of fees by an insurance practitioner, that although, technically, an insurance practitioner is entitled to charge a fee to the patient of another practitioner who, in an exceptional case, applies to him for treatment as a private patient, it is clear that any practice of this sort would tend to be seriously prejudicial to the medical service for the insured.

The Services.

RE-ASSESSMENT OF PRE-WAR DISABILITY PENSIONS.

A QUESTION was recently addressed to the Minister of Pensions, in respect of the re-assessment of pre-war disability pensions of officers who served again in the late war, as it appeared such officers were debarred from any increase of either the service or disability elements of their retired pay, unless the total of such retired pay was less than the service element alone would now be under the new regulations, they were deprived of all compensation for the injuries received in their former service. The Minister was asked whether he would take steps to remove this injustice at once, and whether, as the pre-war Warrant, 1913, Article 561, laid down that these pensions were never to be less than the half pay of the rank, he would apply the new scale of half pay to such cases, pending the settlement of the new standard of disability retired pay, which it had been stated was still under consideration. Major Tryon (Parliamentary Secretary to the Ministry of Pensions) stated in his reply that it was necessary in this matter to distinguish (1) officers disabled before the present war and again disabled by services in it; (2) officers disabled in former wars and not further disabled; and (3) officers disabled by peace service before the present war, and not further disabled. The position of officers was fully considered by the Select Committee on Pensions and was provided for in the Royal Warrants of August 1st, 1917, and July 2nd, 1920; such officers generally gained considerable advantage so long as their disablement by Great War service continued. Officers in the second class could be dealt with under the warrant of Dec. 10th, 1919, the general effect of which was to give the disablement addition allowed by the warrant of 1917 to officers disabled in former wars and still suffering from the effects of such disablement. Article 501 of the pay warrant 1913 or 1914 only entitled the officers to whom it applied to the half-pay rates laid down in the warrant, and not to any higher rates introduced subsequent to the officer's retirement.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lieut. M. B. Macleod to be Surg. Lieut.-Comdr.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lieut.-Comdr. H. L. Murray and J. H. G. Howe to be Surg. Comdrs.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. P. MacKessack retires on ret. pay and is granted the rank of Col.

Temp. Capt. G. Marshall relinquishes his commn. and is granted the rank of Maj.

The undermentioned temp. Capts. relinquish their commns. and retain the rank of Capt. : P. P. Butler, J. Ash, J. E. Thompson, H. F. Stephens, J. Martin, and M. Ashley.

ARMIES OF OCCUPATION.

Capts. J. M. Chrystie and J. G. Morrin relinquish their commns.

1st (Lowland) Fd. Amb. (D.F.).—Temp. Lt. N. M. D Fox relinquishes his commn. and retains the rank of Lt.

3rd (Welch) Fd. Amb. (D.F.).—Temp. Maj. A. Bird relinquishes his commn.

ROYAL AIR FORCE.

Flt. Lt. T. N. Wilthew relinquishes his temporary commn. on ceasing to be employed, and is permitted to retain the rank of Capt.

Lt. R. E. Burns is transferred to the unemployed list.

DEATHS IN THE SERVICES.

Col. C. H. Hale, C.M.G., D.S.O., late A.M.S., who died on June 20th at Portsmouth, aged 59, entered the service in 1887. He served in the Matabele war of 1896 and for his services received the D.S.O. He was an assistant director of medical services during the late war and was awarded the C.M.G. He retired in 1917.

Medical News.

Royal Colleges of Physicians of London and Surgeons of England.—At meetings of Comitia of the Royal College of Physicians and of the Council of the Royal College of Surgeons, on July 28th, diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon 107 candidates (82 men and 25 women) who have passed the Final Examination in Medicine, Surgery and Midwifery of the Conjoint Board, and have complied with the by-laws. The following are the names and medical schools of the successful candidates:—

G. K. Arthur, St. Bart.'s; A. W. Austen, Westminster; Martha F. Barritt, Manchester; Frances S. Barry and Geraldine M. Barry, Royal Free; Marjorie M. S. Bartlett, St. George's; Hylda C. Briscoe, St. Mary's; Lorna P. Brown, Royal Free and Univ. Coll.; G. G. Bruce, Aberdeen; E. M. Burrell, Cambridge and St. Thomas's; A. V. Campbell, Liverpool; F. C. W. Capps, St. Bart.'s; Christabel L. M. Charlesworth, Glasgow and King's Coll.; J. C. Churcher, St. Thomas's; L. E. Claremont, Univ. Coll.; Marion C. V. Clarke, Royal Free; C. S. Cloake and I. J. Corbett, London; R. D. Cowan, Toronto; J. N. Craig, Dundee; E. Cuerel, Lausanne; J. J. da Gama Machado, St. Bart.'s; H. C. de Penning, Bombay and St. Mary's; E. C. Dodds, Middlesex; J. R. Dow, Charing Cross; T. W. K. Dunscombe, Durham; E. R. D. Eastman-Nagle, St. Thomas's; Doris Kathleen Emery, Royal Free; F. T. Evans, St. Bart.'s; J. C. Evans and J. Franks, London; H. Freeman, Westminster, E. St. C. Gainer, Middlesex; P. P. Gandhy, Bombay and St. Mary's; B. Gould, London; Marjorie P. C. Greene, Royal Free; J. F. Hackwood, St. Thomas's; A. H. Hall, Birmingham and London; G. A. M. Hall, Durham; M. Hall, Guy's; B. J. Hallows, St. Bart.'s; G. H. C. Harding, Liverpool; S. Hartley, Oxford and St. Thomas's; S. E. Harvey, St. Thomas's; Marjorie Hawkins, Westminster; M. S. Hashish, Cairo and St. Bart.'s; A. D. Hepburn, Cardiff and Westminster; I. Hipshon, Leeds; R. J. Hodgkinson, Guy's; C. A. Horder, Cambridge and St. Bart.'s; Erna Henrietta Jebens, Royal Free and St. Mary's; L. M. Jennings, St. Bart.'s; Margaret G. Jones, Royal Free; R. C. Lightwood, King's Coll.; D. M. Lloyd-Jones, St. Bart.'s; Eva Lombard, Geneva; Muriel J. Lough, St. Mary's; A. G. Mackay, Edinburgh; D. McClean, St. Thomas's;. C. G. Martin, Cambridge and St. Bart.'s; Enid M. Moore, St. Mary's; L. S. Morgan, St. Bart.'s; J. N. Morris, King's Coll.; R. E. Murray, Calcutta; M. Newman, Liverpool; T. S. North, St. Mary's; H. A. Osborn, Oxford and King's Coll.; Alice Owen, Royal Free; A. Pain, Middlesex; D. B. Pauw, Oxford and St. Bart.'s; Winifred Peacey, Royal Free; L. S. Perera, Singapore and London; Mary W. Pitt-Lewis, Royal Free and St. Mary's; E. Philbin, Manchester; J. H. Porter, Cambridge and Univ. Coll.; J. G. Reed, St. Thomas's; L. M. Rice, Toronto; G. H. Roberts, Charing Cross; A. Robertson, Guy's; Mary F. Roope, Charing Cross; E. Savage, Cardiff and St. Bart.'s; T. Seshachalam, Madras and London; H. Shannon, St. Bart.'s; W. Shaw, Cambridge and St. Bart.'s; A. H. Shelswell, Guy's; S. S. Shri-Kent, Punjab and Liverpool; O. L. C. Sibley and A. I. Silverman, Middlesex; S. R. Shoaika, St. Bart.'s; L. Smalley, St. Thomas's; H. K. Snell, King's Coll.; Dorothy M. Stewart, Royal Free and St. Mary's; Y. A. Sumbul, St. Mary's; Muriel A. Sutton, Univ. Coll.; Marjorie P. Taylor, Charing Cross; Wenefride Thompson, Royal Free and St. Mary's; A. W. Tibbetts, Birmingham; Doris Lyne Veale, Royal Free; A Verwey, Leyden and St. Bart.'s; J. G. Walker, Charing Cross; W. J. G. Walker, Univ. Coll.; L. K. Watson and L. R. A. Wells, Guy's; E. T. Wright, St. Mary's; J. E. Wright, Guy's; and C. F. Young, London.

Diplomas in Tropical Medicine and Hygiene were conferred upon the following 25 candidates from the London School of Tropical Medicine:—

W. Allan, Aberdeen Univ.; J. A. Anklesaria, Bombay Univ.; P. M. Antia, Bombay; S. Bardhan, Calcutta Univ.; W. B. Borden, Maryland, U.S.A.; E. J. Clark, Edinburgh Univ.; K. Comyn, Cambridge Univ and Roy. Army Med. Coll.; S. D. De Vos, Ceylon Med. Coll.; S. F. Dudley, St. Thomas's Hosp.; K. A. Gandhi, Bombay Univ.; L. E. Liat, Singapore Med. Coll.; J. P. Litt, Edinburgh Univ.; T. C. St. C. Morton, Edinburgh Univ.; J. S. Nicholson, Glasgow Univ.; K. S. Nigam, Allahabad Univ.; W. S. Ratnavale, Calcutta Univ.; S. Roach, St. Bart.'s Hosp.; Alice I. Shaw, Calcutta Univ.; H. C. Sinderson and E. T. A. Stedeford, Edinburgh Univ.; W. M. Tough, Aberdeen Univ.; H. M. S. Turner, Guy's; A. M. Walcott, California, U.S.A.; T. B. Welch and N. M. Wilson, St. Bart.'s Hosp.

Diplomas in Ophthalmic Medicine and Surgery were conferred upon the following candidates:—

G. M. Ali, Allahabad Univ.; M. D. Anklesaria and C. R. Athavale, Bombay Univ.; E. R. Chambers, London Hosp.; F. B. Chavasse, Oxford and Liverpool Univs.; R. M. Dickson, St. Andrew's Univ.; G. C. Dixon, Oxford and Manchester Univs.; J. M. Gibson, National Univ. Ireland; E. W. Ingle, Edinburgh Univ.; R. D. Kamdin, Bombay Univ.; L. A. R. V. Koil Thampuran, Madras Univ.; Ida C. Mann, St. Mary's Hosp.; R. R. Mishra and S. S. Mohamedi, Bombay Univ.; R. B. North, Sydney Univ.; P. H. Robinson, Cambridge Univ. and London Hosp.; C. Rudd, Birmingham Univ.; N. L. Sheorey and C. N. Shroff, Bombay Univ.; H. J. Taggart, Queen's Univ.; J. N. Tennent, Glasgow Univ.; and T. H. Whittington, King's Coll. Hosp.

Royal College of Physicians of London.—An ordinary Comitia of the College was held on July 28th, Sir Norman Moore, the President, occupying the chair. Dr. J. Beresford Leathes was admitted to the Fellowship of the College.

The following candidates having passed the required examination were admitted Members: Drs. S. C. Basu, J. V. C. Braithwaite, J. C. Bramwell, W. Brown, A. E. Clark-Kennedy, R. L. T. Grant, D. McE. Kilgour, N. Kletz, H. M. Oddy, H. S. Pemberton, A. Piney, R. J. Reece, L. R. Shore, J. H. Spencer, A. F. Tredgold.

The resignation of his membership by Dr. F. Edge was accepted and an application by Dr. J. J. MacW. Dunbar, asking that the Membership, which he resigned in 1881, might now be restored to him, was granted.—The Dean of the Faculty of Medicine, Edinburgh University, announced that the Murchison Memorial Scholarship for the current year had been awarded to Dr. Jessie McCririe Craig.—The President announced that he had appointed Sir John Rose Bradford to represent the College on the Voluntary Hospitals Commission. On the recommendation of the Council the Baly medal was awarded to Dr. Henry Hallett Dale and the Moxon medal was awarded to Sir Thomas Clifford Allbutt.—The Weber-Parkes prize and medal was awarded to Dr. Louis Cobbett, for his researches on tuberculosis as embodied in his book entitled "The Causes of Tuberculosis."—Dr. Drewitt was appointed a representative of the College on the Committee of Management of the Chelsea Physic Garden, vice the late Sir George Savage.—Dr. Sidney Martin and Sir Arthur Newsholme were re-elected representatives of the College on the Executive Committee of the Imperial Cancer Research Fund.

Royal College of Surgeons of England.—An ordinary council meeting was held on July 28th, Sir Anthony Bowlby being in the chair. Prof. C. S. Sherrington, P.R.S., was admitted as a Fellow of the College under the rule relating to the election of members of 20 years' standing.

A letter was read from Mr. J. S. Rodman, secretary to the National Board of Medical Examiners of the United States of America, transmitting the following resolution passed at the annual meeting of the Board: "Resolved: That whenever a candidate appears before the National Board for examination presenting a certificate from the Conjoint Board in England, the same shall be accepted as a satisfactory qualification for admission to Part III. (practical) of the examination required by the National Board of Examiners."

University of Aberdeen.—At the recent summer graduation the Struthers Medal and Prize in Anatomy was awarded to Dr. Annie Anderson for "Preparations Showing Development of Cerebral Fissures during Fœtal Life." The Lizars Medal in Anatomy was awarded to Edward C. Chitty and William Gunn (equal).

University of Manchester. — The following appointments have been made: Assistant Director of the Physical Laboratories, Mr. J. M. Nuttall, M.Sc. Manch., Senior Lecturer in Physics; Lecturer in Chemistry, Mr. D. C. Henry, B.A. Camb.; Lecturer in Education, Mr. P. G. Reynolds, B.A. Lond. The Cheshire County Council Education Committee have renewed their annual grant of £500 to the University.—The following award has been made: Moseley Memorial Prize in Physics, A. J. Hailwood.—The following representatives of the University on Outside Institutions have been appointed: General Medical Council, Prof. H. R. Dean; Fleetwood Secondary School, Prof. Calder; Bolton School, Colonel E. W. Greg, C.B.; Leek High School, Mr. Herbert Morris; Leek Westwood Hall Girls' High School, Miss Mary A. B. Herford, M.A.; John Rylands Library, Prof Herford and Prof. Kastner; Winwick Educational Foundation, Mr. Geoffrey Owen.

London School of Tropical Medicine.—The following are the results of the examination held at the end of the sixty-sixth session (May to July, 1921):—

*S. Dudley (Surg. Comdr., R.N.) ("Duncan" and "Lalcaca" medals), *K. S. Nigam, *T. C. Morton (Flight-Lieut., R.A.F. Med. Ser.), *A. C. Vardon, *J. P. Litt (Capt., R.A.M.C.), *Lee Ee Liat, *J. Kilian Clarke, *K. A. Gandhi, *E. T. C. Stedeford, *H. M. Stanley Turner, (Wing-Comdr., R.A.F. Med. Ser.), H. C. Sinderson, W. B. Borden (Major, U.S. Army), S. Roach (Surg.-Comdr., R.N.), A. M. Walcott, J. Singh, R. Hunter, F. Dahlerup, W. Milne-Tough, L. B. Perry, R. M. Bharucha, E. J. Clark, R. L. Symes, J. A. Anklesaria, P. M. Antia (Capt., I.M.S.), L. W. Barlow, S. N. Bardhan, J. C. Callanan, H. G. Holdbrook, E. Matthai, W. J. McClintock, J. S. Nicolson, A. C. Paterson, P. Popoff, W. S. Ratnavale, J. A. Ross, A. D. Soares, R. H. Turner, S. de Vos, N. M. Wilson, J. A. A. Duncan, J. Grell, P. R. Lentin, Hassan A. Soud.

* With distinction.

acute discomfort in the knowledge that someone is gazing at a hole in her stocking, a discomfort strictly analogous to that experienced by a person with something to conceal while another stares through "the windows of his soul."

We must admit that here, as in Dr. Russ's first experiment (where the solenoid swings according as the gaze is directed to one or other pole), the effect of the gaze takes place selectively in the *line of vision*, the least deviation of the physiological axis transferring the effect to the new point of fixation. Dr. Russ has omitted to draw the legitimate inference, that the effect is produced at the conjugate focus of the fovea centralis, or on that axis, since if all portions of the retina were equivalent the exact direction of the eye could have no significance, both poles of the solenoid having similar optical and other relations to the retina as to the eye as a whole. This experiment, therefore, indicates that the force (if there be such) emanates from the fovea and from no other part of the eye (at least in appreciable amount), and also, I think, that it is refracted by the optical media in a manner similar to light, although the macula is the most active part of the retina. These considerations and the problems they suggest cast some doubt on Dr. Russ's hypothesis, and the fact that they are not raised by him suggests that experiment has outrun reflection, as may happen with ultra-objective minds. Of course, the theory would look well enough if all retinal emanations could by refraction or otherwise be projected along the axis of macular vision; but though such a supposition is apparently a natural error, the Congress of Ophthalmologists must have known that whatever proportion of such emanations could escape from the eye, and whatever the refractive index of the media to them, they must then be dispersed in proportion as the eye tends to a distant focus.[1] Dr. Russ records incidentally and without comment that the influence was not reflected by a mirror, but does not give us any results to indicate the behaviour of the new force as regards distance of action, so that even this observation is unreliable. The only experiments on its conduction are on transmitting media. He does not study the effect of retinal inactivity through disease, or of opacity of the media, yet these are obvious controls, while the *deviation* of the force would supply a valuable clue to its nature.

It is to be hoped that Dr. Russ will inform us upon these and other points, as, I say, a partly known force supplies a convenient hypothesis which enables lazy thinkers to "pigeon-hole" inconvenient problems, and affords pabulum to the rabble of transcendent theorisers and myth-makers who stand between the people and truth.—I am, Sir, yours faithfully,

IAN D. SUTTIE, M.B., F.R.F.P. & S.Glasg.

Glasgow, August 1st, 1921.

---

[1] Supposing the active retina to be radiant, it is easy to calculate that only about a millionth of this total radiation will be projected upon the pole of the solenoid.

MEDICAL EXHIBITION AT DORPAT, ESTHONIA.—A Medical Exhibition in connexion with the First Esthonian Medical Congress is to be held from Nov. 30th to Dec. 7th next, in the rooms of the Hygienic Institute of the Dorpat University, and has for its object the acquainting of the population of Esthonia with the achievements, resources, and research of medical science as a whole. The Exhibition will comprise the following sections: (1) anatomy, physiology, pathology, forensic medicine, &c.; (2) hygiene, epidemiology, bacteriology, climatology; (3) clinical medicine, therapeutics, surgery, obstetrics, health resorts and sanatoria; (4) venereal diseases; (5) medicamental matters; (6) apparatus and instruments; (7) medical literature. Foreign associations, firms, and individuals are invited to take part, and applications from abroad will be accepted up to August 15th. The Esthonian Government will grant the following facilities to those desirous of participating in this Exhibition. Exhibits from abroad will be free of Custom duty if not sold in Esthonia; no space fee will be charged; free visas will be granted on application to intending visitors to the Exhitition. Further particulars may be obtained on application at the Esthonian Legation, 167, Queen's-gate, London, S.W. 7.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Legislative Programme.

On Tuesday, July 26th, Mr. A. CHAMBERLAIN (Lord Privy Seal), in making a statement to the House of Commons on the Government's programme of business for the remainder of the Session, indicated that the War Pensions Bill was among the measures which it was necessary to pass into law before Parliament adjourned. On the other hand, the Summer Time Bill and the Clinical Thermometers Bill would not be proceeded with further. Among other Bills that the Government would not press—certainly not after 11 o'clock, unless they could be passed with general consent—were the Criminal Law Amendment Bill and the Licensing (No. 2) Bill.

Medical Privilege.

Lord DAWSON OF PENN had given notice of his intention to call attention in the House of Lords on Wednesday, July 27th, to recent rulings as to the privilege of medical men with regard to evidence in Courts of Justice and to move that the matter be referred to a Select Committee of the two Houses of Parliament. He explained, however, that he had received an intimation from the Government that it would be more convenient that the motion should be postponed. He hoped that the postponement, to which he assented, would be for a short time only.

Criminal Law Amendment Bill.

The Criminal Law Amendment Bill was considered on Tuesday, July 26th, by a Standing Committee of the House of Commons, Mr. RENDALL in the chair. On Clause 1, which provides that it shall be no defence to a charge or indictment for an indecent assault on a child or young person under the age of 16 to prove that he or she consented to the act of indecency, Major CHRISTOPHER LOWTHER moved that the age should be reduced to 15.—Major FARQUHARSON, who was in charge of the Bill, said he could not accept the amendment, which was negatived.

Mr. RAWLINSON moved a proviso that "the party so consenting shall be guilty of a misdemeanour." He objected to such grievous power being put into the hands of young girls by the clause as it stood.—Mr. SHORTT (Home Secretary) hoped the Committee would not accept the amendment, which might have the effect of defeating the real objects of the Bill.—On the suggestion of Earl WINTERTON the amendment was amended so as to limit its operation to young persons of 15 years. This was agreed to by 17 votes to 12.

An amendment, moved by Mr. RAWLINSON, to Clause 2, omitting a subsection providing that reasonable cause to believe a girl was of or above the age of 16 shall not be a defence to a charge of seduction was rejected by 21 votes to 4.—Major CHRISTOPHER LOWTHER moved that the subsection should apply only where it was proved that up to the time the offence was committed the girl was *virgo intacta*.—Sir RYLAND ADKINS said it would be quite impracticable to apply such a test, and the amendment was withdrawn.

Sir RYLAND ADKINS moved the omission of the subsection extending the time for taking proceedings under the clause from 6 to 12 months after the commission of the offence.—The amendment was agreed to.

Sir R. THOMAS moved an amendment on Clause 3, which increases the penalties to which persons summarily convicted of brothel keeping, &c., are liable, providing that any such person who was an alien should, in addition to any such punishment under the clause, be recommended for deportation.—The amendment was agreed to, as was also a new clause, moved by the same hon. Member, providing that any alien convicted of procuring or attempting to procure should be recommended for deportation, in addition to receiving the punishment already provided by law.

The Committee stage of the Bill was concluded, and the Bill was ordered to be reported to the House.

HOUSE OF LORDS.

TUESDAY, JULY 26TH.

Coroners (Remuneration) Bill.

The Coroners (Remuneration) Bill was read a third time and passed. [On Thursday, July 28th, the Royal Assent was given to this Bill, as well as to the Dentists Bill, the Public Health Officers Bill, the National Health Officers Bill, and the Health Resorts and Watering Places Bill.]

HOUSE OF COMMONS.

WEDNESDAY, JULY 27TH.

Appointments of Medical Referees.

Mr. MYERS asked the Minister of Pensions whether, seeing that the original appointments of medical referees were

Wilfred W. E. Fletcher, M.B.Camb., D.P.H., who died on July 31st after an operation, was for 25 years a medical inspector of the Local Government Board and had lately acted as medical officer of health for the Metropolitan Borough of Hackney.

SPIRIT DUTY (VOLUNTARY HOSPITALS) GRANT.—The Ministry of Health and the Scottish Board of Health are prepared to receive applications from voluntary hospitals for grants in respect of payment of duty involved by the use of duty-paid spirit or drugs containing duty-paid spirit for medical and surgical purposes in these hospitals during the year 1920.

BETHLEM ROYAL HOSPITAL.—A course of lectures and practical instruction for the Diploma in Psychological Medicine of the Universities of London, Cambridge, Durham, &c., will begin at the Bethlem Hospital early in October next. Syllabus and further particulars may be obtained on application to the Physician Superintendent.

ABERDEEN SICK CHILDREN'S HOSPITAL.—A market fair in aid of this hospital was held on Saturday, July 30th, in the policies of Durris House, the seat of Mr. H. R. Baird. Over 20,000 people were present. Sir James Taggart, in opening the fair, said that Mr. Baird's aim was to raise £1000. The market was reminiscent of the old-time country fairs. In a large marquee in the centre of the meadow were neatly-laid-out stalls, heavily laden with china, fancy goods, flowers cut and in pots, cakes, fruit and vegetables, jumbles, pictures, furniture, rabbits, eggs, and the like. There were the usual attractive side-shows, including a fortune-teller and an aerial flight. Along with special donations the total amount realised was over £1000.

SUMMER COURSE IN HELIOTHERAPY AT LEYSIN.—The programme of the course already announced to be given by Dr. Rollier and his collaborators at Leysin, Switzerland from August 16th to 20th is as follows:—

Les bases scientifiques de l'héliothérapie. Etude physique et biologique de la lumière (Dr. Rosselet).—La pratique de l'héliothérapie des tuberculoses chirurgicales et ses résultats cliniques (Dr. Rollier).—Le diagnostic radiologique des tuberculoses ostéo-articulaires et le contrôle radiographique des résultats cliniques de l'héliothérapie (Dr. H. J. Schmid).—La cure de travail et l'avenir des convalescents de tuberculose chirurgicale. L'héliothérapie préventive (Dr. Rollier).—Les adjuvants de l'héliothérapie (radiothérapie, photothérapie artificielle, &c.). L'héliothérapie des affections non tuberculeuses.—Les appareils orthopédiques utilisés pour l'héliothérapie (Dr. Amstad).—Héliothérapie et peau (Dr. Leuba).—Visite des établissements héliothérapiques du Dr. Rollier et présentation de malades (Drs. Rollier, Amstad, Alexandrowski, Miéville et Giauque).—Visite et démonstration de "l'Ecole au soleil" (Dr. Rollier).

The course is gratuitous. Board and residence will be reserved for participants at 10 frs. a day, early application to be made to Secrétariat médical du Dr. Rollier, Les Frênes, Leysin-Village, Switzerland.

Dr. F. J. Waldo, City Coroner, held an inquiry on July 19th into the fire which broke out on the evening of July 8th at 52, Aldersgate-street, premises within the danger zone, in the possession and occupation of the Kolynos Incorporated, makers of dental cream. Dr. Waldo announced that he had received a number of letters from residents and occupiers in the immediate neighbourhood protesting against the storage of dangerous and combustible material in such a congested area. Mr. Norman L. Elliott, surveyor in the works department of the London County Council in charge of the means of escape section, said he had inspected the premises after the fire, and was not satisfied with the means of exit. He advocated arrangements being made between owners of adjoining premises for the erection of bridges from building to building. Mr. Paterson, H.M. Inspector of Factories, said that when he visited the premises in March, 1920, he thought the exits were reasonable. A warehouseman said to him the cause of the fire was a complete mystery unless it was a fuse. The electric light machinery was running at the time of the fire.

Giving particulars of the substances stored on the premises when the fire broke out, Mr. John Melvern, B.Sc., of Muswell Hill, chemist to the company, stated that there were 250 gallons of alcohol, 2½ tons of glycerine, between 50 and 100 lb. of thymol, a considerable quantity of eucalyptus oil, and three cases of peppermint oil. Superintendent Sells, of the Clerkenwell Fire Brigade, stated that the business carried on in the building caused a great risk to the neighbours, and Colonel Fox, of the Salvage Corps, described the exits as "most unsatisfactory, the roof access being a dangerous fire trap." At another inquiry recently held by Dr. Waldo on a fire at 33, Whitecross-street, the fact was elicited that people employed on the lower floors could not use the fire escape to the roof because the occupiers of the upper floors were not at work that day.

Obituary.

JAMES WALKER DOWNIE, M.B., C.M. GLASG., F.R.F.P.S. GLASG.

Mr. James Walker Downie, who died at Shandon on July 21st, was a native of Glasgow, and after being educated at the High School entered the University, where he graduated M.B., C.M. in 1881. After a period of study of diseases of the ear, nose, and throat in London he returned to Glasgow to take up junior appointments at the Royal and Western Infirmaries. He was soon appointed lecturer on diseases of the nose and throat at the Western Medical School and lecturer in the University, and later became surgeon to the Western Infirmary and to the Royal Hospital for Sick Children, to which at the time of his death he was consulting surgeon. He had been consulting laryngologist to the Ochil Hills Sanatorium and was for some time a member of the Medical Consultative Committee of Consumption Sanatoria of Scotland.

Mr. Downie became a Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow three years after graduating; he examined for the Faculty in aural surgery and presented it with a handsome mace. He was an honorary president of the Glasgow University Medico-Chirurgical Society, ex-president of the Scottish Otological and Laryngological Society, and an ex-vice-president of the British Laryngological and Rhinological Association. He made frequent contributions to local societies and was the author of a clinical manual for the Study of Diseases of the Throat.

Appointments.

ABEL, A. LAWRENCE, M.S. Lond., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Kensington and Fulham General Hospital.

NICORY, C., M.R.C.S., L.R.C.P. Lond., House Surgeon to Torbay Hospital.

PAVEY-SMITH, A. B., M.C., M.B., B.Ch. Camb., F.R.C.S. Eng., Surgeon for Nose, Throat and Ear to the Royal Bath Hospital and Rawson Convalescent Home, Harrogate.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Jun. M.O. £500.
Barnsley, Beckett Hospital.—Jun. H.S. £200.
Bedford County Hospital.—H.S. £200. Asst. H.S. £150.
Birmingham General Hospital.—Res. Anæsthetist. Obst. H.S. H.S. Each £100. H.S'.s to Spec. Depts. £125. Res. Surg. Officer. £180.
Birmingham, Queens' Hospital.—Honorary Surgeon.
Bradford Royal Eye and Ear Hospital.—Hon. Asst. Ophth. Surg.
Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.
Bristol Royal Infirmary.—Cas. Ophth H.S.'s £120.
Carlisle Non-Provident Dispensary.—Res. M.O. £300.
City of Leeds.—Asst. M.O.H. £650.
City of London Maternity Hospital, City Road, E.C.—Res. M.O. £100.
Deptford Metropolitan Borough.—M.O.H. £800.
Devonport, Royal Albert Hospital.—H.S. £200.
East Suffolk County Education Committee.—Female Asst. Sch. M.O. £500.
French Hospital and Dispensary, 172, *Shaftesbury-avenue, W.C.*—Anæsthetist. £25.
Glasgow, Bellahouston Ministry of Pensions Hospital, Cardonald.—M.O. £350.
Glasgow, District Mental Hospital, Gartloch, Gartcosh.—Jun. Asst. M.O. £350.
Glasgow, Victoria Infirmary.—Visiting Surgeon.
Glasgow, Woodilee Mental Hospital, Lenzie.—Asst. M.O. £350.
Great Northern Central Hospital, Holloway, N.—Dental Surg.
Great Yarmouth Hospital.—H.S. £200.
Hull Royal Infirmary.—V.D. and Cas. O. £250. Asst. H.S. £150.
Kensington and Fulham General Hospital.—Hon. Phys. Res. M.O. £200. Non-Res. Surg. £100.
Kent County Council, Lenham Sanatorium.—Asst. M.O. £400.
Leeds, Hospital for Women and Children.—Two H.S.'s. £25.
Leeds Public Dispensary.—Sen. Res. M.O. £250.
Lincoln Education Committee.—Asst. Sch. M.O. £500.
Liverpool, Royal Southern Hospital.—Surg. Tutor and Registrar. £20. Second M.O. to V.D. Dept. £200. Two H.P.'s. Three H.S.'s. Each £100.

governing the price at which whisky could be sold to the public; whether he was aware that the present high price of whisky was due to the fact that the Government took 8s. 5½d. per bottle from the price paid by the consumer for whisky 30 per cent. under proof; and would he explain the reason for the continuance of this imposition.—Mr. **BALDWIN** (President of the Board of Trade): This matter is under consideration.

Infantile Mortality in British Guiana.

Mr. **STEWART** asked the Secretary of State for the Colonies the latest statistics as regards infantile mortality in the Colony of British Guiana, and the figures showing the population to-day in comparison with recent years; whether the lack of population could be in any way attributed to defective sanitary administration which, owing to the low-lying nature of the coast-line, was imperatively necessary; whether the present insanitary conditions were due to the lack of proper administration on the part of the executive or to a lack of proper sanitary laws on the part of the legislature.—Mr. **CHURCHILL** replied: In British Guiana the rate of mortality of infants under one year was 223 per 1000 in 1918 and 185 per 1000 in 1919. The returns for 1920 have not yet been received, but may be expected shortly. The figures for 1918 were adversely affected by shortage of food caused by the war. The population was 278,000 at the census of 1891, 296,000 at the census of 1911, and was estimated at 306,000 in 1919. Sanitary work in the coast-strip is heavily handicapped by natural conditions, as the cost of good drainage is often prohibitive. Improvement in sanitary conditions which will continue to engage my careful attention depends, in my judgment, principally upon the general development of the colony—with regard to which I am in consultation with the Governor. There is no restriction as regards the nationality of foreign immigrants other than ex-enemies.

MONDAY, AUGUST 1ST.

Officers' Pensions and Medical Fees.

Major **GLYN** asked the Financial Secretary to the War Office whether, when an officer commuted his pension, after having undergone a medical examination, he would consider a revision of the costs charged as a fee, which at present varied from £1 to £10, to a uniform figure of £2, in view of the fact that this sum was said to be charged to defray the cost of the medical examination, which necessarily was of the same character for all cases; and whether Clause 9 of the form of instructions to officers in the army on this subject, dated July, 1920, might be amended accordingly.—Mr. **HILTON YOUNG** replied: I think that the method of charging a fee bearing some relation to the amount of the sum for which the pension is commuted is, in all the circumstances, the most equitable method, and I am unable therefore to revise the regulations in the manner proposed.

Insanitary Milk Transit.

Mr. **CHARLES EDWARDS** asked the Minister of Health whether his attention had been called to the complaints of dairymen to the effect that milk churns were often transported in guards' vans and luggage vans which were not suited to the carriage of milk in hot weather, with the result that much milk was wasted because it turned sour in transit, and that the health of the infant population suffered from the shortage; and whether he could take any steps to induce railway companies to provide better facilities for the conveyance of milk.—Sir **ERIC GEDDES** replied: Neither my right honourable friend, the Minister of Health, nor I have received any complaints of the nature indicated, but I shall be pleased to inquire into any specific instances which may be brought to my notice.

Suicide and War Neurosis.

Mr. **MYERS** asked the Minister of Pensions what was the total number of suicides among the in-patients of pensions institutions for war neurosis: whether certain institutions had a higher record in this respect, and why; and whether there was sufficient staff, medical, nursing, and orderly, in such institutions to lessen the painful occurrences of suicides.—Mr. **MACPHERSON** replied: I understand that out of the very large number of patients who have received treatment for neurasthenia in Ministry institutions, there have been eight cases of suicide, and that in no institution has there been more than one such fatality. In no case was it found that there was negligence or inadequate supervision, and I am satisfied that every reasonable precaution is taken to guard against these distressing occurrences.

Naval and Military Medical Appointments.

Commander **BELLAIRS** asked the Financial Secretary to the Admiralty how many medical officers in the navy held appointments, whether administrative or clerical, where they are not practising their profession in the direct treatment of human ailments and injuries.—Mr. **AMERY** replied: Eight medical officers of the naval service hold appointments of a clerical or administrative nature where they are not called upon to undertake the direct treatment of human ailments or injuries, but I may point out that the duties of these officers include the examination of candidates for entry and the survey of invalids, &c., which is essentially work for a medical officer. There are also five naval health officers, whose work, while not involving direct treatment as defined by the hon. and gallant Member, should be classed under the heading of preventive medicine.

Commander **BELLAIRS** asked the Secretary of State for War how many medical officers in the army hold appointments, inclusive of India, where they are not practising their profession in the direct treatment of human ailments and injuries.—Sir **L. WORTHINGTON-EVANS** replied: The total number of medical officers in the army at home and abroad (excluding India) who are not practising their profession in the direct treatment of human ailments and injuries is 166—the whole of the remainder being employed in direct treatment of human injuries and ailments. The 166 officers include those employed as professors and instructors at the Royal Army Medical College and elsewhere; those employed in preventive medicine, hygiene, and other scientific subjects, and in the medical examination, inspection, and training of recruits, and also 26 officers doing duty in territorial schools of instruction and in administrative medical posts with territorial divisions. I regret that similar information for India is not readily available, and could not be obtained without reference to that country.

Medical Service of the Air Force.

Commander **BELLAIRS** asked the Secretary of State for Air whether his Council was attempting to build up a separate medical service from the Army and Navy; if so, how many medical officers were there; whether casualties or invalids were sent both to naval and military hospitals, or exclusively to military hospitals; and whether any hospitals had been or were being built for the Air Force.—Captain **GUEST** replied: The answer to the first part of the question is in the affirmative, and to the second part, 124. This figure excludes medical officers employed at the Air Ministry. With regard to the remaining parts, casualties and invalids are sent, where possible, to the nearest naval, military, or civil hospital. No hospitals have been or are being built for the Royal Air Force, but Royal Air Force hospitals have been established in buildings at Halton and Cranwell which were formerly occupied by other units. In addition, a temporary hospital for officers exists at Avenue House, Finchley. The latter is a private house, hired for the purpose, and has not been altered.

TUESDAY, AUGUST 2ND.

Women Panel Doctors.

Sir **WALTER DE FRECE** asked the Minister of Health if he would state how many women physicians were at present acting as panel doctors; and, in that case, how many patients they had on their lists.—Sir **ALFRED MOND** replied: 117 women physicians are at present acting as panel doctors in England and Wales and the number of patients on their lists is 40,686.

Working Expenses of Army Hospitals.

Captain **WEDGWOOD BENN** asked the Secretary of State for War what was the reason for the increase in the charges for educational establishments and working expenses of hospitals and depôts in the Estimates for the present year.—Sir **L. WORTHINGTON-EVANS** replied: I understand the question to refer to the total of Head III. of the Estimates entitled "Cost of Educational, &c., Establishments and Working Expenses of Hospitals, Depôts, &c.," which shows the full cost of the various Army institutions and establishments for which working expense accounts have recently been instituted under the new system of Army accounting. The increases as compared with 1920-21 are mainly due to two causes; firstly, as in the case of depôts, to the expansion of this sub-head to include classes of depôts not previously costed; and secondly, as to the case of the schools and technical establishments, to fuller information, disclosed by the new accounts as to the actual cost of these institutions, including such items as stores consumed and rental value of the properties. Notes will be found on the explanation pages of the estimates opposite each individual institution, and in any particular case I shall be happy to supplement the information there given as far as possible.

THREAT OF FAMINE AND PELLAGRA IN U.S.A.—A large portion of the Southern cotton belt is apparently in danger of serious food shortage and an epidemic of pellagra. The President is stated to have instructed public health and Red Cross authorities to ascertain what relief can be afforded by the Government. The difficulty of selling cotton has resulted in a shortage of money, and many thousands of people are apparently deprived of the foodstuffs which protect against this disease.

as possible on his road. A short description of an individual case will probably afford the best illustration.

Example of a Complaining Patient.

Miss A. was an unattractive woman past middle age, with a large fibrotic goitre and an inoperable recurrence of carcinoma of the breast. When seen at the end of November, 1920, the left breast was solid with growth, there was some ulceration of the new growth at the site of the operation on the right breast, and many nodules of growth were scattered over the right chest wall. She was very depressed, and full of complaints about her nurses, her food, and the cheerlessness and discomfort of her room. She was not confined to bed, but appeared to spend the whole of her time sitting by the fire and thinking. She found difficulty in concentrating her attention upon a book, she had hardly any visitors, and there were no relatives or friends who would find house-room for her. She was thus thrown back almost entirely upon her own resources. These included an affectionate regard for a niece in a convent school in France, and a sense of gratitude towards a distant relative who was providing for her maintenance in a nursing home; beyond these she seemed to have no interests outside shopping, life in a comfortable boarding house, and travelling about London. She displayed little emotion in talking about her own illness, except when expressing her sense of grievance against the doctor (since dead) who had first diagnosed the case, because he had not concealed his diagnosis from her.

She was asked to face the facts (admittedly known to her) that she had cancer, that most people with cancer die, and that it was probable that she would do as others had done. At the second visit she refused to see me, but I was informed that she was much more cheerful and stronger and had been out visiting friends. (Her internal conflict had become external—if she could only avoid this brutally truthful doctor she could feel as if she were getting well.) During the following three weeks I saw her seven times and we became good friends, though she continued to cherish grievances against her nurses. Her strength increased at first, but later diminished, and by the New Year was was finding difficulty in getting up. Her dislike of the matron and of her special nurse was now intense, and during the first week in January she began to have definite delusions of persecution and disturbing dreams.

Growth of Phantasy.

She was now entirely unable to leave her bed, and began rapidly to lose touch with the world of external fact. The cheery conventionalities of the nurse and of her few visitors were now thoroughly unreal to her, and the life of her dreams and phantasies became for her the real life, disturbed by occasional shadowy perceptions of taking nourishment, having her bed made, or receiving a visitor. She was evidently worried and unhappy, and she had a moderate amount of physical pain. Without external help it seems probable that at this point she would have withdrawn completely from contact with external affairs; she would have spent her remaining strength in a lonely struggle against insuperable difficulties in the land of phantasy. But with the help of a pre-established personal understanding and a readiness to talk in the language of her own phantasy, I was able to accompany her and to help her to overcome her difficulties. She recounted to me her dreams; many or most of them were half-waking dreams, more properly described as phantasies.

Three dreams recurred frequently in various guises: (1) Of lying at night in a sanctuary; (2) Of struggling to get somewhere; (3) Of people with a motor plotting against her. The patient evidently derived great comfort from recounting these dreams to a sympathetic listener, but she often had difficulty in talking, and would not take the trouble to give associations. It was therefore necessary to guess at the interpretation, and to wait for confirmation in subsequent dreams before making use of any information so gained. Also, since the interpretation of the dream was left for the time being in the region of the unconscious, it was necessary when one did make use of it to speak in the language of the unconscious.

Thus, when she first dreamed that people with a motor were plotting against her by the road-side, it seemed probable that the dream had reference to arrangements for her own funeral. This interpretation became more probable when she dreamed on the following night that the people in the nursing home were plotting to take her away in "a motor or something." She recounted this first as a dream, then as a statement of fact. I told her that I had sent for her niece, who was coming to take care of her. She replied: "It will be no use. I shall be taken away before she comes." I promised to keep in close touch with everything that went on at the home, and assured her that she certainly would not be taken away before my visit to her on the following day. This veiled statement that she would live for at least 24 hours completely relieved her anxiety, and I left her sleeping comfortably. The mention of the word "death" might have excited the alarm conventionally proper to such an occasion.

On the following day she reported a night full of dreams of frantic struggles to get somewhere, so as not to be lost. They all ended in the nurse flinging her roughly on the bed. She was persuaded to see that the nurse was only doing her duty in looking after her. On the following day she had still been struggling all night to get somewhere and still always finishing with the nurse, but now as a rescuing angel and not as a pursuing demon. On the evening of the same day she took a great liking to the nurse and made friends with her old enemy the matron. At the same time she became contented and pleased with all her surroundings and with herself. She had been a very difficult patient and had worn out the patience of those around her, and this sudden change of front on her part no doubt gained for her a considerable increase of comfort and attention.

A Dream of "Home."

The next day she continued her policy of reconciliation; she sent for a priest and was received into the Roman Catholic Church. On the same night she had a dream which linked together most of her previous dreams and was probably for her the solution of her life problem. It was as follows: "I was in a place with high, thick, moss-covered walls, with pretty little white lights scattered about in the walls. In one part there were beautiful strings of beads hanging down over the stone. We all lay or sprawled upon the floor until midnight in night-dresses or chemises. The place was beautiful, but its effect was rather weird and frightening. Then I think I must have been in a boat in this place, because there was water underneath. I went out in a boat or on a bed and was struggling up a hill to make money. (On inquiry, she was sure it was a great struggle, though she was not herself rowing or doing anything.) I went on and came down the other side of the hill, but finished at the same place as I had started from, which had now become this room, and I called it home." She dreamed this dream several times with slight variations, but always finished at home, and was always "so glad to get there." When the niece arrived she gave an account of a watchnight service to which she had taken her aunt a year or two previously, and which had evidently supplied much of the imagery of this dream.

For several reasons it seemed probable that the place from which the patient started in this dream was at once her mother's womb, Mother Earth, and Mother Church. She set out from it on the voyage of her life, which was always an uphill struggle to obtain creature comforts, yet a struggle which demanded effort from others rather than from herself. She had followed her course right up the hill and down the other side, but was now surrendering her life to the common stock of human life whence it had come, to Mother Church whence it had come, to Mother Earth whence it had come, and was very glad to get home again.

Cessation of Mental Conflict.

The niece recognised this as a correct summary of her aunt's life-history. With the help of the knowledge of the patient's attitude of mind derived from this dream, it was comparatively easy to keep in touch with her mentality during the remaining days of her life. The niece was instructed to abandon all reticences and to talk quite freely in her aunt's presence, assuming that she knew of her approaching death and welcomed it. Her death had appeared to be imminent, but after this solution of her conflicts there was a very definite return of physical strength, and on the first day of the remaining week of her life her voice, from an almost inaudible whisper, became strong enough to carry across the room. She then grew steadily weaker until her death. She slept peacefully at nights, and during the days was perfectly conscious and seemed quite happy. She said that her sleep was natural; she thought she had pleasant dreams, but could not remember them. During the last three days she could only make herself heard with great difficulty, but she intimated that she liked best to hear her niece and a friend talking to each other about everyday affairs in the room, and on the last day she expressed herself as quite ready to die. She was fully conscious half an hour before her death, and died—apparently without any discomfort—in her sleep.

Physical pain was never a very prominent feature in this case, but there was considerable and increasing pain during December, and a little T. opii was given; after the solution of the mental conflicts, however, the pain ceased entirely, and no sedatives were required. During the last fortnight the patient appeared to have entirely forgotten the existence of her growth, and no mention was made of it or of any pain. There is no doubt that the last week of this patient's life was quite exceptionally pleasant and satisfactory both to herself and to those around her, and it

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—The following candidates have passed the Final Dental Examination, and have been granted the diploma L.D.S. R.C.S. Edin. :—

Sidney Sack, James D. C. Archibald, Michael J. Quinlivan, Gerrit Johannes Lamprecht, Esias Andries Nortje, Raymond Levey, James S. Wilson, William Gunn, and Leonard Lees. Douglas G. Munro passed in the subject of Medicine and Surgery.

UNIVERSITY OF GLASGOW.—The following degrees were conferred on July 18th :—

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Thomas F. Arnott, John Barlow, Alexander K. Bowman, Thomas M. Burton, Donald S. Campbell, Thomas C. Christie, Percy B. Farrar, Lennox M. Johnston, Alexander A. Kirkland, James R. Learmonth (with honours), William M. McCash, John M. McKenzie (with commendation), Alexander H. McLean, George L. Mitchell, G. W. St. Clair Ramsay (with commendation), Rebecca E. Roulston, William L. Templeton (with commendation), Ernest J. T. Thompson, James Watt, John C. Watt, Jeanie L. D. Wilson, and Robert McLaren Wilson.

NATIONAL VETERINARY MEDICAL ASSOCIATION.—Dr. O. Charnock Bradley, of Edinburgh, was re-elected President of the Association at the annual meeting at Chester, on July 27th.

WALSALL HEALTH COMMITTEE.—The Ministry of Health has withdrawn on grounds of economy its sanction to a scheme of the Committee to provide an open-air pavilion for consumptive children in the borough.

LITERARY INTELLIGENCE.—The Roll of War Service of the University of London Officers Training Corps just being published by the Military Education Committee of the University, at 46, Russell-square, London, W.C., contains the names and particulars of 665 fallen officers who were members or former members of the Contingent. A second section records 1726 honours and distinctions awarded to 1068 officers, including V.C., 5; D.S.O. with bar, 5; D.S.O., 45; M.C. with two bars, 3; M.C. with bar, 41; M.C., 497; D.F.C., with bar, 1; D.F.C., 9; A.F.C., 10; Mentioned in Despatches, 584 (twice, 97; thrice, 19; four times, 6; five times, 2; six times, 1); foreign awards, 114. The third section gives particulars of 4276 officers and former officers and cadets of the Contingent who served as officers in the war. The price is one guinea in cloth binding, packing and postage 1s. extra. Other bindings are available.—Mr. Henry Kimpton is publishing the following new books and new editions: Diseases of Children, designed for the use of students and practitioners of medicine, by Herman B. Sheffield; Physical Diagnosis, by W. D. Rose, 2nd edition, revised and enlarged; Tuberculosis, and How to Combat It, by F. M. Pottenger.

DONATIONS AND BEQUESTS.—Mr. John Graham Rodger, of Beacon Hill, Liverpool, former member of the Mersey Docks and Harbour Board, has left the following bequests. The bequests, besides others, include £5000 each to the Liverpool Royal Infirmary, Northern Hospital, Royal Southern Hospital, Bluecoat Hospital, Woolton Convalescent Institution; £2000 each to the Liverpool Merchants' Guild, Home for Female Incurables, and Myrtle-street Children's Infirmary; £1000 each to the Indigent Blind School, Mount Pleasant Consumption Hospital, Eye and Ear Infirmary (West Kirby), Children's Convalescent Home.—The late Mr. John Bevan Morgan, of Llanelly, Carmarthen, has left £750 to the Llanelly Hospital, and £25 each to the Carmarthen Infirmary, the Deaf and Dumb Institution, Swansea, and the Institution for the Blind, Swansea.—By will the late Mrs. Susan Mary Harries, of Wem, Salop, left £300 each to the Royal Salop Infirmary, the Wolverhampton Orphanage, and the Home for Incurables, Leamington; and £200 to the Shropshire and North Wales Eye, Ear, and Throat Hospital.—By will the late Mr. John Dyer, of Richmond Villas, Swansea, left £1000 to the Swansea General and Eye Hospital for furthering the endowment of the Dyer Ward, but from which 7s. 6d. per week is to be paid to the matron for the purchasing of flowers, fruit; and sweets for the children; £1000 to the North Devon Infirmary, Barnstaple; £500 each to the Swansea Infirmary for the Blind, the Deaf and Dumb Institution, Swansea, and several other charitable institutions.—The St. Mary's Hospitals, Manchester, have received legacies of £160 from the executors of the late Mr. Thomas Groom Baker and £200 from those of the late Mr. Joseph Core. The Manchester Royal Infirmary also received a legacy of £600 from the late Mr. Baker, and other donations from several sources to the amount of £200 have been received. The "Golliwog days" in aid of the Ancoats Hospital on May 27th and 28th have resulted in a sum of £525 being paid over to the hospital.—The Chelsea Hospital for Women has received £25 from the Mercers' Company and £26 5s. from Sir S. B. Provis towards the building of its Nurses' Home. £16,000 have now been received, leaving £13,000 still to be collected.

MEDICO-LEGAL SOCIETY.—The following dates have been arranged for meetings of the society during the session 1921–22:—1921: Oct. 18th, Nov. 15th, Dec. 16th (annual dinner). 1922: Jan. 17th, Feb. 21st, March 21st, April 27th, May 30th, June 29th (annual general meeting). Members are desired to make a note of these dates.

UNIVERSITY OF PARIS.—A revisional vacation course on Recent Ideas concerning Diseases of the Digestive Tract will be given in the amphitheatres Trousseau and Bichat, Clinique Médicale de l'Hôtel-Dieu, from Sept. 12th to 23rd. The course will be under the direction of Prof. Maurice Villaret, and will comprise 30 lectures, divided into four main sections of Explorations, Symptoms, Diseases, and General Treatment. A certificate will be issued to students who complete the course, for which the fee is 150 frs.

VITAL STATISTICS IN FRANCE.—In France last year the excess of births over deaths was 159,790, as against 58,914 in 1913. For the first time since the war statistics have been available for the whole of the country, including the three departments of Alsace Lorraine. The births were 834,411 last year, compared with 790,355 in 1913, an increase of 44,056. The deaths were 674,621 against 731,441 in 1913, a decrease of 56,820. The number of marriages was almost doubled—623,869 last year against 312,036 in 1913.

TREATMENT OF SURGICAL TUBERCULOSIS IN BRISTOL.—For some time past the Bristol City Council, advised through its health committee by the medical officer of health and the tuberculosis officer, has had under discussion plans for the institutional treatment of surgical tuberculosis. There has been some difficulty in securing adequate premises, and in consequence of this difficulty it was at one time proposed that Bristol should as a temporary measure rent beds at Alton, while a more permanent home was being secured in or near Bristol. This plan has, however, been disapproved by the Ministry of Health under the pressure of the economy campaign, and although the Bristol Health Committee is anxious to proceed with the Alton proposal its fate is for the time being uncertain. At the time when it was first mooted this proposal was criticised on the ground that economy and efficiency can be reconciled only by a policy of concentration rather than one of diffusion. These critics are, through the medium of the Bristol Medical Committee, likely to secure a hearing before long, and it is possible that even if the Alton plan should fail other proposals may be forthcoming by which delay in the provision of the necessary premises may be obviated. The Bristol Council is proceeding with the more permanent part of its plan, the development of an estate of 70 acres on the outskirts of the city recently purchased in order to provide 100 beds for the treatment of "pre-tuberculous" children. In the meantime temporary premises leased to the Council by the Bristol Guardians are being used to their utmost capacity under the direction of the City Tuberculosis Officer, Dr. C. J. Campbell Faill, for the treatment of tuberculous lesions, pulmonary as well as surgical, in children, but these premises are grievously inadequate.

HOSPITAL FOR TUBERCULOUS CHILDREN, BELFAST. The Belfast Corporation has opened a new hospital for tuberculous children at Graymount, a few miles from the city on the north side. The property includes a commodious mansion, formerly the residence of Major Kerr-Smiley, M.P., and 15 acres of land with well-laid out pleasure gardens. It overlooks Belfast Lough. There are ten large airy wards with accommodation for 50 patients, a number which will be increased as soon as circumstances permit. The institution is intended for the non-pulmonary forms of tuberculosis, especially for cases of bone and joint disease. Attached to the hospital is an operating theatre and a workshop for the manufacture of splints. There is also an open-air day school which is attended by contact cases—i.e., children from homes where cases of tuberculosis exist. These children spend the day at the hospital and are provided with two meals. They are taught the elements of housewifery, simple dress-making, knitting, &c. Miss Jolly is matron, and the attending surgeon is Mr. H. P. Malcolm.

The opening ceremony was performed on July 22nd by the Lady Mayoress of Belfast, and the principal speakers were Sir E. Coey Bigger, Chief Medical Inspector to the Irish Local Government Board, and Prof. Thomas Sinclair. The former mentioned in the course of his speech that one half the cost of maintaining the institution would come from the city rates and the remaining half from Government funds. He pointed out that there was a decided decline in the incidence of tuberculosis in Ireland. In the ten years ending 1910 the average number of deaths from tuberculosis was 11,627, while in 1920 the total deaths were only 7420, a reduction of 33 per cent. He urged more attention to the milk-supply with the view of stamping out the bovine type of tuberculosis. Prof. Sinclair expressed the opinion that better results were obtained in surgical tuberculosis by open air and hygienic measures than by operative procedure.

hospital helper who contracted small-pox during his work. In the summer the hospital flew the Red Cross flag for two weeks in readiness to receive wounded from the fighting 30 miles to the southward, but the few casualties which occurred were sent to Tientsin. The famine spread through neighbouring districts in the autumn and the Mission undertook the distribution of grain under the auspices of the North China International Society for Famine Relief. An outbreak of pneumonic plague ten miles south of Tsangchow took place at the end of the year, at which time the earthquake, very serious elsewhere, was slightly felt in the neighbourhood.

A couple of pages of the report deal with the women's hospital. The difficulty occasioned by the suspicious attitude of many of the patients is partly overcome by the plan of allowing each patient one relative or friend to live in the hospital and wait on the patient. A great hindrance to medical work is the well-known ability of the Chinese to suffer uncomplainingly for long periods of time; many patients are only brought to hospital in a hopelessly advanced stage of disease. Tuberculosis and cancer are common, and all treatment is prejudiced by the absolute lack of sanitation in the homes of the poorer people. A lack of funds prevents the undertaking of more extensive work.

A MEDICO-EDUCATIONAL EXPERIMENT.

IN the medical report which has been issued on the Oak Bank Recovery Home opened at Prestwich in October, 1917, by the Invalid Children's Aid Association, for ailing children, Dr. A. A. Mumford, the medical adviser to the Home, gives an account of the work done and of the principles of treatment adopted.

Earlier experiments in 1913–14 had shown the importance of steady and definite out-door occupation in establishing a permanent recovery in ailing children, better results following a shorter and fully occupied stay in the country than a longer and unoccupied stay in a convalescent home. Dr. Mumford notes that the final test is to be found in the ultimate fitness of the child for citizenship, and points out that the measurement of respiratory capacity forms a reliable index to the standard of will-power as well as that of bodily health in a given individual. On this axiom is based the treatment for the ailing and delicate children admitted to Oak Bank Recovery Home. Careful notes are taken of the range of breathing of all the children, most of whom on admission possess barely the minimum of respiratory capacity to suffice for a sedentary life, and although they are not encouraged to put forth exaggerated respiratory efforts, nor is any formal training given to this end, yet, after a sufficiently prolonged stay the range of breathing is found to be greatly increased. The benefits resulting from the acquirement of adequate respiratory capacity are claimed by Dr. Mumford to be far more permanent than are those derived from the usual forms of Swedish drill. Tables are appended to the report, suggesting that the longer the stay of the child the better the results as gauged by the breathing tests, the nature of the tests applied, however, not being specified.

Dr. Mumford correlates with these observations similar observations made upon children at the Greengate Dispensary, Salford. These children, who are suffering from actual deformity of the chest, associated with a severe degree of rickets, receive the same treatment as do the Oak Bank Home inmates, without the advantage of country air; and after three or four years of treatment they are usually discharged, not only completely cured but above the average in general health. Dr. Mumford concludes by the remark that improvement in class work is constantly associated with increased range in breathing.

WORTHING WATER-SUPPLY.

THE Worthing Corporation is wise in the step it has just embarked upon in preparing for the increased demands that must inevitably be made upon it in the near future as regards that all-important commodity, water. Worthing grew in population more than any other urban district in West Sussex in the decade 1901–1911; the figures of the population were 22,567–30,308 respectively; and while the 1921 census figures are not yet available they must, as the result of changed circumstances since 1911, show a very large increase in population, inasmuch as a considerable extension has been made of the boundaries. The demands for water have consequently greatly increased. The works from which Worthing obtains its present supply are situated at Broadwater, at the foot of the South Downs, and were constructed a quarter of a century ago. At that time the Local Government Board stipulated for a daily yield of 1,000,000 gallons before sanctioning the loan to cover the cost. The supply proved ample and of excellent quality, but during the past ten years, consequent upon the increased population and the extended district, the average daily consumption has increased from about 900,000 gallons to 1,050,000 gallons, or at the rate of only about 15,000 gallons per day per annum. In a week of maximum use the average daily supply rises to about 1,300,000 gallons, an increase of about 25 per cent. This is approaching very closely to the maximum yield of the existing works, which at the end of a series of dry years may fall even as low as 1,300,000 gallons per day. Acting, therefore, on the advice of Mr. Kenneth P. Hawksley, consulting engineer of Westminster, the corporation has, without a word of opposition, voted in principle for a scheme to make ample provision for the future at a cost of £80,500. But this formidable sum is not to be raised at once, nor in the immediate future, but steps are to be taken forthwith for acquiring the land only and then piecemeal the construction of the works and the provision of the necessary machinery. In the first place, efforts are to be made to secure an additional flow of water from the excellent source already tapped at Broadwater; while the new site upon which the corporation has designs for an extension of their water-getting area is in the same vicinage as the existing works and known as the Long Furlong Valley. There is no doubt this will result in an abundant supply of water as excellent as that from the Broadwater site. The South Downs are noted for their excellent springs. A few miles eastward of Worthing the large towns of Brighton and Hove are supplied with water from similar sources. Worthing may be congratulated upon its foresight.

A. P.—We are informed that the site for the proposed Lister Memorial has not yet been decided upon.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, August 8th.—12 noon, Dr. S. Pinchin; Diseases of the Heart. 2 P.M., Dr. Morton: X ray Department. Mr. MacDonald: Surgical Out-patients. Mr. Gibb: Eye Department. 4.30 P.M., Lecture:—Dr. A. Saunders: Scurvy.

TUESDAY.—10 A.M., Mr. D. Buxton: Dental Department. Surgical Registrar: Demonstration of Cases (Surgical Wards). 11 A.M., Dr. McDougal: Electrical Department. 2 P.M., Dr. Burrell: Medical Out-patients. 4.30 P.M., Lecture:—Dr. Pritchard: Acute Pyogenic Infections.

WEDNESDAY.—10 A.M., Mr. MacDonald: Genito-Urinary Department. 12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen. 2 P.M., Mr. Addison: Operations. 4.30 P.M., Lecture:—Mr. Page: Anæsthesia.

THURSDAY.—11.30 A.M., Obstetrical Registrar: Gynæcological Demonstration. 2 P.M., Dr. S. Pinchin: Medical Out-patients. Mr. Simmonds: Orthopædic Department. 2.30 P.M., Dr. A. Saunders: Demonstration of Cases, Medical Wards. 4.30 P.M., Lecture:—Mr. MacDonald: Bladder Growths.

FRIDAY.—12.15 P.M., Dr. Burnford: Applied Pathology. 2 P.M., Mr. Simmonds: Surgical Out-patients. Dr. Pernet: Skin Department. 2.30 P.M., Dr. Pritchard: Visit to Medical Wards. 4.30 P.M., Lecture:—Mr. D. Buxton: Dental Emergencies in General Medical Practice.

SATURDAY.—10 A.M., Dr. A. Saunders: Medical Diseases of Children. Dr. Burnford: Visit to Medical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients.

Daily:—10 A.M., Visit of Post-Graduates to Wards. 2 P.M., In-patient, Out-patient Clinics, and Operations.

Births, Marriages, and Deaths.

BIRTHS.

EARP.—On July 22nd, at Onex, Geneva, Switzerland, to Kathleen, (née Goodliffe) wife of J. Rosslyn Earp, M.A., M.R.C.S. —a daughter, who was named Evelyn Mary.

HARTIGAN.—On July 28th, at Wood Hatch, Farnborough, the wife of Colonel J. A. Hartigan, C.M.G., D.S.O., R.A.M.C., of a daughter.

JEPSON.—On July 24th, at a nursing home, the wife of W. Baly Jepson, M.C., M.R.C.S., St. Bartholomew's Hospital, of a daughter.

NORBURY.—On July 29th, at 25, Harley-street, the wife of Lionel E. C. Norbury, O.B.E., F.R.C.S., of a daughter.

WINFIELD.—On July 27th, wife of Dr. F. B. Winfield, of Harborne, Birmingham, of a daughter.

MARRIAGES.

BUTCHER—DYER BALL.—On Thursday, the 28th July, at Blackheath, Trevor A. Butcher, O.B.E., M.R.C.S., L.R.C.P., to Lucy, only daughter of the late James Dyer Ball, I.S.O., Hong-Kong, and Mrs. Ball, 55, Lewisham-hill, S.E.

HUDSON—BASTOW.—On June 19th, at St. Alban's Church, Burnaby, B.C., W. F. A. Hudson, M.A. (Cantab.), of Fosthall, Nakusp, B.C., to Irene Bastow, M.B., B.S. of 12, Cardiff-road, Luton, Beds.

NAPIER-CLAVERING—SPRIGGE.—On July 23rd, at Stoke Poges Church, by the Rev. Canon A. T. Barnett, Mark, elder son of Mr. and Mrs. Claude Napier-Clavering, of Harborne, Birmingham, to Elizabeth, elder daughter of Sir Squire and Lady Sprigge, of Stoke Green, Slough.

DEATHS.

ALLEN.—On July 23rd, 1921, at Riversdale, Belper, Richard G. Allen, M.R.C.S. Eng., L.R.C.P. Edin.

ATKINSON.—On July 25th, at Bexhill-on-Sea, Frederick Page Atkinson, M.D., formerly of Surbiton, aged 80.

LYON-SMITH.—On July 29th, at 35, Harley-street, W., Harry Lyon Lyon-Smith, M.D., of heart failure.

WILSON.—On the 19th July, at St. Martin's House, Jersey, suddenly, Fleet-Surgeon George Wilson, Royal Navy (Retired).

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

CRIPPLES HOSPITAL, HARTSHILL.—On July 21st Lady Stafford formally opened the nurses' wing at the Hospital of the North Staffs Cripples Aid Society, Layfields, Hartshill. The foundation stone of the new block was laid by Sir Joseph Cook, now acting Premier of Australia, some time ago, the building being then intended for an operating theatre, but the necessity for better accommodation for the nurses was so urgent that temporary arrangements were made for the theatre. Although the cost of the addition has been largely raised already, the hospital requires a greatly increased annual income. If sufficient funds were available the work could be greatly extended. The income for last year was about £9000, the annual expenditure about £12,000; 198 patients passed through the wards, an increase of 34 on the previous year; 805 new out-patients presented themselves for treatment, and the average attendance in the out-patient department was 5076 per month. An average of 161 visits per month was made to the homes of patients. Pensioners are paid for by the Government, and all voluntary income is spent upon the children.

Notes, Short Comments, and Answers to Correspondents.

PHANTASIES OF THE DYING.

SOME REMARKS ON THE MANAGEMENT OF DEATH.

BY J. NORMAN GLAISTER, M.B., B.S. LOND.,

CHIEF ASSISTANT, MEDICAL O.P.D., ROYAL FREE HOSPITAL.

IT is commonly assumed that the function of the physician is to restore the disordered health of his patient to a normal condition, but it is difficult precisely to define a normal condition. It is obvious that a physical condition normal for a man of 65 is not normal for a boy of 15; it is almost equally obvious that the normal condition for a man aged 150 is one of peaceful slumber in a churchyard. The suggestion here brought forward is that we should regard death as being, like birth, a natural process; by so doing we shall escape the futile struggle, well known to every general practitioner, against a death known to be both inevitable and desirable.

The method of dealing with a dying patient here described will not improbably be criticised on two grounds: (1) That there is nothing new about it—up to recent times it has been usual for the priest to attend to the mental comfort of the dying, and he can do so still where it is considered necessary; (2) that it is new and unnatural and an undesirable intrusion into the privacy of last moments. Such criticism would encourage me in the belief that the provision of mental comfort for the dying has been a preoccupation of the human mind from the earliest antiquity, and that present-day practice falls far short of what it might achieve in the fulfilment of the legitimate demands of a deep-rooted human instinct.

Mental State Associated with Inoperable Cancer.

For the sake of simplicity let us confine our attention to the typical case of a patient dying from inoperable cancer. Consider first the mental state usual in such a case. The illness of the patient is steadily progressing; his friends know that he is dying, but he is supposed not to know—or at least, not to know how advanced it is. He is perfectly sane, presumably capable of drawing inferences from his own observation of facts, and growing steadily worse; the efforts of those about him to dissuade him from taking his illness seriously are in marked contrast with their earlier attitude of urging him to seek thorough treatment. The atmosphere of unreality soon shuts him off completely from the world of common-sense and normal conversation; the word "cancer" is never mentioned, and the friends avoid any remarks which might encourage him to ask a direct question as to the verdict. Soon the outsider listening to a conversation between the patient and his friends will notice the most elaborate circumventions on both sides; each speaker is obviously preoccupied with "cancer," and draws attention to it negatively by his avoidances.

The patient's mind is therefore in a condition of continual conflict. He knows that he is dying of cancer, and this for him is very likely the most important fact in the world; it appears constantly in his dreams, but in the waking world there is not a living soul with whom he can discuss it. He tries to exclude it completely from his conscious and rational thinking. His conventional life and his intercourse with other people are based upon the supposition that he may soon get well; his inner life is based upon the exactly opposite supposition. Again, as in every case of extreme illness, the instinct to accept death is steadily growing stronger; but all his intercourse with others tends to accentuate the instinct of self-preservation natural to the healthy, which his friends persistently force upon him. The one thing which he craves—human companionship up to death as in normal life—is denied him. As the end approaches, the effort of those around him to encourage him becomes such a mockery that it is abandoned; but there is nothing to put in its place. There is no objective which the patient can now pursue in common with those around him, and he sinks into lonely phantasy. The rôle of the doctor is to treat symptoms, to prolong life as far as possible, and to relieve physical pain by morphine or otherwise. For all human purposes the patient is thus thrust out from the company of living minds and buried away from contact with his kind weeks or even months before his death.

The method here advocated aims at providing human companionship for the patient up to the last moment of consciousness; it relieves fear by showing a desire to share his dreams and phantasies, and to accompany him as far was urged that every effort ought to be made to pursue this direction, and to institute similar work at as many centres as practicable without waiting for the legislation requisite to enable arrangements in other directions to be made. [Dr. Bond then offered suggestions as to how best to bring this about.] On the lines suggested, a very valuable amount of out-patient work could be put in hand, not only without expenditure but at a saving of public funds.

Widening the Scope of Treatment by Voluntary Admission.

To make clear the meagre extent to which voluntary in-patient treatment is available, it may be pointed out that of the three kinds of institutions for the insane—county and borough mental hospitals, registered hospitals (the 13 supported by voluntary contributions), and licensed houses—only the registered hospitals and licensed houses can receive voluntary admissions, and that, as 86 per cent. of the 22,000 patients annually admitted into all institutions for the insane go to the county and borough hospitals, it is obvious that such voluntary treatment as the law allows is, indeed, almost negligible. The procedure for voluntary admission into the registered mental hospitals is commendably simple, is entirely free from formality, but is subject to notification and supervision by the Board of Control. It has worked well, and there would seem no valid reason why it should not be made equally as simple for licensed houses, or why it should not be extended to the county and borough mental hospitals, where it is, in point of fact, most urgently needed, and still more generally—such as, to general hospitals, other suitable institutions, properly organised nursing homes, and to single care: always provided that supervision is adequate. Subject to this proviso, there is some reason to think that notification of the patient's admission without mention of name would be sufficient—which would accord with public sentiment and tend to popularise early and preventive treatment—and to doubt whether even notification of each admission is necessary as respects public hospitals and those supported by voluntary contributions. Legislation on these lines would meet the necessities of the first subdivision of certifiable cases—those cases which, for sake of brevity, are here termed the "willing," and some of the arrangements could then at once be made, again without incurring fresh expenditure.

Permissive Legislation to Authorise Retention.

But legislation to widen the scope of voluntary treatment would only very partially alleviate the present position. To be effective, either therapeutically or educationally, it should take note of and mitigate the hardship of the law's present attitude towards those members of the second subdivision of certifiable cases—namely, the "indifferent"—whose mental illness is in an early stage and is presumably recoverable. In soliciting sufficiently comprehensive legislation, it should always be remembered that the many who have the mind to volunteer for treatment, but whom the law does not permit to do so—the "willing"—and the very many more who are too ill to object—the "indifferent"—but whose responsible relatives have every confidence in the treatment proposed though objecting to certification as a preliminary step, together constitute the majority of recoveries from certified attacks of mental disorder; that these recoveries number some 35 per cent. of the total admissions: and that, of these recoveries, 44 per cent. take place within six months of the alleged commencement of the illness, and 73 per cent. within a year. It is on behalf of both these types of cases, the "willing" and the "indifferent"—but not on behalf of the "unwilling" nor with respect to protracted cases among the "indifferent"—that urgent appeal should be made for legislation which would permit medical freedom of action for a short, but sufficient, time in which recovery may take place—a period of six months has been suggested, to be extended on adequate grounds. The desired legislation would authorise, without certification, admission and retention but not detention; it would be permissive in character and would not necessarily impose expenditure of money upon any authority; though to complete the scheme on comprehensive lines, educationally as well as therapeutically, considerable expenditure would probably be necessary later and when funds are available. Under such permissive legislation opportunity would, in the meantime, be afforded to test, if need be, the soundness of the proposals. Surely those of the public who, in the face of such limited and reasonable proposals, still raise objections on the score of the liberty of the subject are making liberty a travesty and a despotism raised out of a will-o'-the-wisp abstraction.

The Consultative Council's Scheme.

On the assumption that this relief by legislation will sooner or later be granted—but not until then—it may readily be seen how admirably the Consultative Council's scheme can serve the requirements of psychological medicine:—

Domiciliary service, it is true, will continue to be but little employed in mental cases until undergraduate instruction in the subject is better provided for; after which the general practitioner can be counted upon as a powerful agent in promoting mental hygiene. *Primary centres*, where provided with out-patient departments—but only if so provided—could render signal service in the treatment of early cases and in preventive work. *Secondary centres* would serve the same purpose, and should also provide mental in-patient service—but, pending the legislation referred to, they cannot do the latter; adequate in-patient accommodation involves the erection, or provision by adaptation, of psychiatric clinics as annexes to general hospitals; their erection would involve expenditure which it is useless to urge at present. The *University centres* (with teaching hospital and medical school) would afford, but with greater elaboration, the same facilities as at secondary centres, and in addition would supply organised undergraduate and post-graduate instruction, the latter leading to a diploma in psychological medicine: for teaching purposes, besides arrangements for the more purely scientific subjects, a clinical triad is needed—psychiatric clinic, neurological department, and the public mental hospital and institution for mental defectives; in addition, instruction should be accessible in mental hygiene of childhood, in criminology and the psychological aspect of industrial hygiene.

It is at the university centres that present efforts should be concentrated, and it is here, when money is available, that the first psychiatric clinics should be erected: an obvious opportunity exists here for the intervention of someone interested in this great need and generously disposed.

Regarded as supplementary services, our public mental hospitals (the 97 county and borough mental hospitals, with over 100,000 beds, the 13 voluntarily supported hospitals, with over 2000 beds, and the as yet few institutions for defectives) constitute no mean asset in any general scheme of medical and allied services. While emphasis can be laid on their general excellence, any defects or deficiencies should not be lost sight of. [Dr. Bond here took the opportunity to ventilate such matters as classification of patients, dietary, freedom of egress, clinical facilities and records, and the medical staff—including (i.) the institution of a visiting staff as consultants in branches other than mental, (ii.) the better organisation of the resident staff, and (iii.) their at present restricted position in the public service.]

Fluidity of Service Desirable.

While regarding each of these three items relating to the medical staff as of much moment, the position in the public service of the resident medical staff of public mental hospitals and institutions for defectives may be urged as a matter of the highest importance, and, apart from securing legislation, as the key to any chance of progress. At present they are restricted seems not unreasonable to attribute the fact to the special attention devoted to the solution of her mental difficulties.

The Necessity for Plain Speaking.

An immense amount of skilled effort is directed towards the extirpation of malignant disease, to the great advantage of those patients who are cured as a result; but unhappily most of those attacked remain uncured, and to these we seem to be able to offer comparatively little that is of value to them. Has not the time arrived for a broad re-survey of the whole treatment of the inoperable cancer case? Operative procedures of great value for the prolongation of life and the relief of discomfort have of late been described, but in very many cases the patient cannot be given the benefit of such treatment because it is considered necessary to maintain the fiction that there is no question of cancer, or alternatively that the growth has been permanently disposed of by a previous operation. When cancer has been diagnosed the facts in their least painful guise ought to be laid before the patient, and this may be a mental operation of considerable difficulty. The patient and his medical attendant can then discuss adequately their plans for extirpating the disease, or failing that for making the best possible use of the remainder of life, with all the help that the surgeon, the radiologist, and the psychologist can give them.

"PETROMORTIS."

POISONING by the exhaust gas of motor engines has already been the subject of comment in these columns (see THE LANCET, 1920, i., 1334). In the House of Lords the Marquis of Aberdeen commented recently upon the emission of noxious vapours from motor vehicles, suggesting the need of amending the Light Locomotive Acts so as to bring the matter under the control of the police authorities generally, when it was pointed out by the Duke of Sutherland (replying for the Minister of Transport) that the County Council could make regulations for the parks under their control similar to those which ruled in the great London parks, and that the police and London County Council possessed powers under the Locomotives on Highways Act to take proceedings against owners of motor vehicles that emitted smoke.

The London County Council have on various occasions exercised these powers. The visible emission of smoke from motor vehicles is certainly a cause of discomfort to other users of the road and sometimes interferes with vision, and constitutes a nuisance and a risk which should be stopped. The offence is due either to excessive lubrication or to an imperfect explosive mixture, the result of using a low-grade petrol or benzol without the sufficient addition of air. Whenever an explosion in a petrol engine is of moderate intensity and the combustion is incomplete, the exhaust gases will contain an increased percentage of carbon monoxide, which may rise to 15 or 20 per cent., while the percentage of carbon dioxide will correspondingly be lower.[1] According to Haldane 0·05 per cent. of carbon monoxide in air may produce symptoms of poisoning, 0·1 per cent. will cause headache and palpitation, while 0·2 per cent. is absolutely dangerous. Carbon monoxide is invisible and merely detectable by the symptoms it produces if inhaled. It is lighter than air, and so when emitted from a moving car will ascend and quickly become diluted. It is only when through a leak in the exhaust pipe that it escapes into a closed car, or where engines are run in imperfectly ventilated garages or, as during the war, in dugouts, that serious results have ensued.

Lieut.-Colonel Dale Logan, D.S.O., R.A.M.C. (retired),[2] Dr. R. P. Albaugh,[3] and A. C. Foote[4] have published accounts of serious results that have thus been caused. Automobilists using closed cars who develop headache after long runs would do well to eliminate this possibility. In America there have been a large number of deaths in small garages, with windows and doors closed, when engines have been run for testing purposes. There the term "petromortis" has been used by the press as to the cause of death in cases of this kind.

THE WEST RIDING MEDICAL CHARITABLE SOCIETY.

THE 93rd annual meeting of this Society was held at Sheffield on July 28th under the presidency of Prof. Arthur J. Hall. Reference has been made in former years to the valuable work carried on by this Society. Founded in July, 1828, at a meeting held in Leeds, it has gone on steadily increasing its sphere of usefulness. The Society now numbers 826, last year's increase of 63 being the largest in any one year. Those desirous of being admitted members of the Society must be in good health and not over 40 years of age. No application for a grant can be given except in respect of a member who has been an annual subscriber for at least five years. As is stated in the rules, the objects of the Society are as follows: "To help (*a*) any member who is *disabled by illness*, or accident, or age, and who has not adequate means of support; (*b*) the widow or children of a member dying in indigent circumstances; (*c*) the mother of such member, being a widow (or the sister, being single or a widow), who has acted as his housekeeper for a period of not less than five years immediately preceding his incapacity or death; (*d*) in the education of the children of members thus disabled."

The great majority of members join from altruistic motives and the Society deserves the support of every practitioner in the West Riding who is entitled to join. On the other hand, it is a wise and provident act for all young medical men and women to become members of this Society, for they know that if evil days fall upon themselves or upon those who are dear to them, and for whom they may not have been able to make provision, they will not be left without sympathy and help. The feature of the annual meeting is the careful consideration of the applications for help. The applicants are all known intimately by the stewards of the particular district in which they reside and full details of their circumstances are brought before the meeting. The grants are made for one year, each grant being subject to revision. Many of the grants have been running for long periods, one of them for 35 and one for 40 years. On this occasion 15 grants were made amounting to £1843. It was some years before the Society with its humble origin was able to make any grants at all, and it is a gratification to the members to know that the total sums granted now amount to £69,197.

ENGLISH–ESPERANTO DICTIONARY.

ESPERANTO was designed by a Polish ophthalmologist, Dr. Zamenhof, as an international link of communication. To-day medicine itself is becoming more and more recognised as a bond uniting the peoples of the world, and so it is natural that there should be many Esperantists among medical men. These will welcome a new and enlarged English–Esperanto dictionary,[1] containing some 30,000 entries. This number of words can, however, be considerably extended by the Esperanto student, as prefixes and suffixes play a very important part in the construction of the language. A feature of the dictionary is the printing in a separate line of every word having a distinct though allied meaning. For example, the word entertainment is repeated three times for the separate significations of hospitality, amusement, and soirée. Some new roots have been introduced which the authors offer for the acceptance of students, *tanko*, the armoured car introduced during the war, and *kamufli*, to camouflage, being examples; but not everyone will approve of the list of neologisms. *Pulo*, for instance, which is given for the name of the game played with billiard balls as well as for pool in the commercial sense, has long been in use by Esperantists for flea, and is indeed an international root, being derived from *pulex*. Although there is a fair proportion of technical words which the average educated man is expected to be acquainted with, there are not many medical terms, save those which are in more or less common use. There is a convenient list of proper names. Such a dictionary has long been wanted by Esperantists.

A MISSION HOSPITAL IN CHINA.

Prof. Harold Balme, dean of the School of Medicine, Shantung Christian University, brought the claims of preventive medicine in China before a large gathering of visitors to the British Medical Association gathering at Newcastle on July 22nd. We have before us the annual report for 1920 of the Roberts Memorial Hospital, Tsangchow (Province of Chihli), which contains a brief account of the extension of the main hospital work by the establishment of temporary branch hospitals, and gives some idea of the enormous amount of work undertaken by these outposts of Western medicine. Members of the hospital staff spent three weeks during the spring of the year under review in the city of Hsien Hsien, 50 miles distant from Tsangchow, and the capital of a county containing over 1000 villages and 320,000 people; and during those three weeks 2130 out-patients were attended to and 219 operations performed (112 of them under chloroform anæsthesia) in makeshift surroundings; two deaths only occurred—one of an out-patient, who drank "a week's supply of medicine at one go," and the other a Chinese to a temperature of 80° C., and is then condensed in vacuo at 50° C. for about three hours to a viscid fluid. The method, though not quite so satisfactory in retaining all the vitamins as my process of evaporation at room temperature, would be more practicable on a large scale.

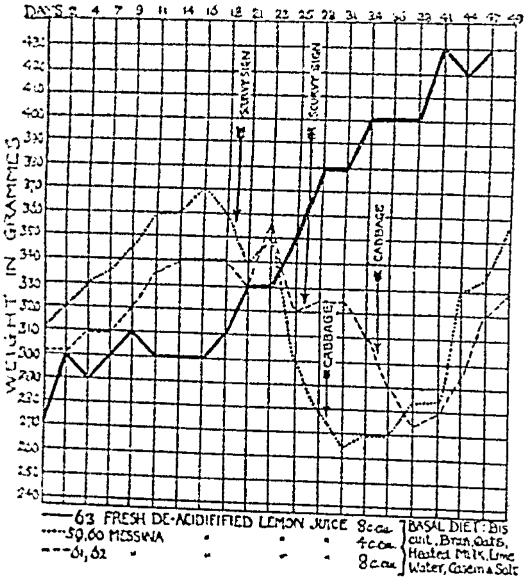
During the past months a sample of lemon juice extracted from the whole lemon at Messina has been received and tested at the R.N. College, Greenwich. The fluid was turbid and contained some of the rind oils; it appeared to have undergone some changes since collection. This, when strained and de-acidified and used in quantities up to 8 c.cm. daily, had absolutely no preventive effect. The scurvy symptoms came on early, and were even more marked than usual from the 15th to the 21st day, and death occurred unless an efficient antiscorbutic was given. A control which received the same quantity of de-acidified juice prepared from fresh lemons in the laboratory showed no signs and steadily gained weight (Chart 2). A second sample of lemon juice from Messina which had been preserved with potassium metabisulphite gave equally bad results when tested biologically.

CHART 2.



Tinned tomatoes have been found by M. H. Given, H. B. McClugage, and A. F. Hess[3] in America, to have very definite antiscorbutic powers; these have not, so far as I know, been tried in England. They form a very palatable and excellent food. It seemed desirable to carry out some experiments here, for such food might easily be included in the ration of sea-going ships under special conditions. The animals were placed on the usual basal diet, and to this was added daily 4 c.cm. of the tinned tomatoes from brands bought in the open market. The guinea-pigs very quickly got used to the new addition to their diet, and ate it with avidity. When it was used as a prophylactic the animals steadily gained weight; in others, which had been allowed to develop definite scurvy symptoms with marked wasting, it rapidly established a diminution of the symptoms and a steady gain in weight, the results being excellent. Charts are given showing curves of the various experiments, but full protocols of all the animals under examination are not included for want of space.

Conclusions.

1. The tablets prepared in the cold have retained their efficiency for over 12 months.
2. Commercial lemon juice made from the whole fruit received from Messina, which had not been specially protected from heat, had lost all its antiscorbutic properties when tested in England, confirming the work of Miss Alice Davey.[4]
3. Tinned tomatoes in doses of 4 c.cm. act efficiently against scurvy in guinea-pigs, both as a prophylactic and a curative agent.

SCURVY:

A SYSTEM OF PREVENTION FOR A POLAR EXPEDITION, BASED ON PRESENT-DAY KNOWLEDGE.

BY A. H. MACKLIN, M.D. VICT.,
AND
L. D. A. HUSSEY, B.SC. LOND., A.K.C., F.R.ANTHROP. SOC.,
MEMBERS OF THE SHACKLETON-ROWETT EXPEDITION; LATE MEMBERS OF THE SHACKLETON ANTARCTIC EXPEDITION.

SCURVY has played a very prominent part in the history of Polar exploration, and a close examination of records shows that its presence or absence has borne a close relationship to success and failure. In the light of recent knowledge it is probable that many of the tragedies which have occurred were due to scurvy, though the condition was not recognised or reported as such at the time. It may easily be understood that in the preparation for a modern expedition the prevention of scurvy is a most important consideration, and an account of the actual steps taken may be of some interest. Until quite recently little attention has been directed to this and other deficiency diseases by the bulk of the medical profession in the British Isles, where cases of adult scurvy in an advanced condition have been very rare; and the signs of early scurvy are so indefinite that they are difficult to recognise, unless they occur simultaneously amongst a large body of people leading similar lives, and under conditions where its onset might be expected.

There are several reasons for the interest which has been aroused. Numerous cases occurred in Europe under the severe conditions of famine imposed by the war, and allowed of unprecedented opportunities for its study by medical men in the different zones. Moreover, much greater attention has recently been directed to infantile scurvy and the factors influencing its onset, especially the effects on milk of drying and preserving processes, and the possibly detrimental effects of pasteurisation and sterilisation.

Modernity of Deficiency Diseases.

It was formerly the custom to regard pathological changes as due always to the addition to the system of some harmful foreign substance; the discovery that functional disturbance and tissue changes may be due to the lack of some essential body has opened up a new conception of the ætiology of disease. Moreover, deficiency diseases are to a great extent modern diseases, due to the tendency of people to crowd together into large towns, which necessitates the comparatively large use of preserved foods. It has been very fully demonstrated that these essential bodies or "vitamins" are present in foods in the natural state and in fresh condition, but that their functional activity is much diminished or totally destroyed by many preservative processes. Since the war remarkable interest has been aroused, and the word "vitamin" figures largely, not only in medical literature, but in the advertisement columns of the daily papers, and has almost become a household term, though its meaning is by no means always clear.

Early Antiscorbutic Data.

The apathy and lack of general interest which formerly existed with regard to these subjects made things very difficult for those responsible for the organisation of past expeditions; moreover, the

Presidential Address

(ABRIDGED)

ON

PSYCHOLOGICAL MEDICINE:

ITS POSITION IN MEDICAL AND ALLIED SERVICES.

Delivered before the Medico-Psychological Association

By C. HUBERT BOND, C.B.E., D.Sc.,
M.D. Edin., F.R.C.P. Lond.,
COMMISSIONER OF THE BOARD OF CONTROL, AND EMERITUS LECTURER IN PSYCHIATRY AT MIDDLESEX HOSPITAL MEDICAL SCHOOL.

Dr. Bond began by claiming justification for the selection of this topic on account of the widespread interest incited by some of the problems presented during the war in connexion with cases of nervous and mental breakdown, and the fact that sufficient time has now elapsed for the necessary stride forward in which to take stock of the war's lessons, to appraise the permanency of any apparent change[1] in incidence of mental maladies, and to revise demands—shaped at first on idealistic lines—in conformity with available resources.

The restraining influence of the nation's straitened circumstances would, he said, have rendered the subject impossible of selection, but for the conviction that an unfortunate amount of mental therapy is being neglected, and that a large proportion of it can be successfully undertaken without fresh expenditure of money. As an incentive to put in hand what can now be overtaken—delay in doing which is negligent—and to make quite clear what is required either financially or by way of legislation before the remainder of the work can be even commenced, something in the nature of a thoroughly understood scheme of mental medical service seemed wanted. A scheme for general medical services, including several special ones, but with very small reference to psychological medicine, having been propounded from an authoritative source—the Consultative Council on Medical and Allied Services, established under the Ministry of Health Act of 1919—it seemed desirable to take this as a basis for consideration how best to give effect to the dictum that the mental health of the nation was of no less moment than its physique.

The Council's report, and the reports of the Welsh Council, the Council of the Scottish Board of Health, and of the Irish Public Health Council were reviewed by Dr. Bond, to emphasise the small extent to which the growing needs of psychological medicine had so far been considered on anything like comprehensive lines, despite the rising interest in mental disorders and in the maintenance of mental health—of which interest several notable examples were cited. At the same time note was taken of a regrettable falling-off, during at least the last ten years, in the financial support hitherto given to mental hospitals (13 in England and Wales) supported by voluntary contributions; as a consequence there were now many persons of good education and social standing being treated in public mental hospitals in association with others without these qualifications, whereas these 13 hospitals were founded specially for such cases. For lack of funds the hospitals were not able to do anything like the amount of charitable work they once did, and often were unable to add the structural arrangements demanded for modern lines of treatment. This want should be made widely known, for these excellent hospitals had a fine record worthy of generous support.

Lunacy Laws in Relation to Mental Treatment.

Dr. Bond then went on: So much misunderstanding still prevails, both in professional and lay circles, concerning the legal aspect of the topic, that before attempting to show what comprehensive arrangements should be aimed at, which of these can be made forthwith and which must await either legislation or the removal of financial restrictions or both, it seems advisable to set the legal position out afresh and once again to make clear how the Lunacy Laws, while designedly protecting the liberty of the subject, obstruct the adequate treatment of mental disorders and render improvement in schematic organisation impossible—save in one direction. The easiest way to understand the matter, I suggest, is to consider mental cases as administratively divisible into (*a*) the uncertifiable, and (*b*) the certifiable (under either the Lunacy or Mental Deficiency Acts), and the certifiable cases as subdivisible into (i.) the "willing" (those who have the mind to recognise they are mentally ill and desire treatment), (ii.) the "indifferent" (those who are too mentally ill to raise any objection to proposed treatment), and (iii.) the "unwilling" (those who, whether they recognise their mental illness or not, are hostile to any curtailment of their liberty involved in treatment). Ostensibly the law puts no obstacles in the way of either out-patient or in-patient treatment for uncertifiable cases; nor does it with respect to out-patient treatment for certifiable cases. With respect to both classes of cases, that indeed is an accurate statement as regards out-patient treatment. But the dividing line between uncertifiability and certifiability is notoriously thin, and the former condition readily, and often suddenly, passes into the latter; so that, in practice, fear of incurring penalties attached to undertaking in-patient treatment contrary to the provisions of the Lunacy Acts (section 315 of the Act of 1890) results in a large number of uncertifiable cases receiving no treatment, and in inadequate arrangements for it; and therefore the position of uncertifiable cases in need of mental treatment as in-patients cannot be ignored. It is, however, in connexion with in-patient treatment for certifiable cases that the law, because of the public's dislike of certification, proves such a hindrance to early treatment and obstructs the making of arrangements on lines which will conduce to treatment being sought more promptly, to better study and increased research in mental disorders, and therefore to all-round progress in the specialty. The obstruction lies in the fact that, excepting the almost negligible amount of voluntary treatment permitted, which is restricted in place to the mental hospitals supported by voluntary contributions and to licensed houses, in all three classes of certifiable cases—i.e., not only the unwilling, but also the willing and the indifferent—certification must be carried out before any form of in-patient treatment can be legally secured.

Importance of Out-patient Treatment.

It is thus manifest that the sole direction in which an extension of existing mental medical service can be made without legislation is in out-patient work—preferably at general hospitals. Such work is in progress at some of the London hospitals and at a very few provincial ones. A notable example of what can be done in this sphere may be cited in the work going on in the out-patient department of the Radcliffe Infirmary at Oxford, details of which will be given later in a paper to the Association by Dr. T. S. Good. It amount of importance has been given to heat, and that oxygenation has played a more important part. The following are extracts from an article appearing in THE LANCET, March 5th, 1921:—

---

[1] For example: While during the quinquennium 1910–14 the average number of female direct admissions into institutions for the insane and into single-care (in England and Wales) was 11,668, or a ratio of 6·21 per 10,000 population, the average number during the three war years 1915–17 was 10,894—i.e., a ratio of 5·59 per 10,000: but the admissions during the years 1918–20 were 11,687, 12,060, and 12,003 respectively, with corresponding ratios of 5·93, 6·15, and 6·07: and it may be of some significance that, while in pre-war years there was no marked seasonal or monthly variation in the number of admissions and such as obtained was never high in November, yet in 1918, while the number of female admissions in September and October were respectively 7·2 and 7·8 per cent. of the total female admissions during that year, the percentage during November was no less than 10·1, and the maximum number of reception orders made on any given day occurred on the day following the Armistice. These figures, for what they are worth, have been restricted to females because those relating to males would be vitiated by the large number of the male population serving with the Forces.

> It was found that bubbling air at ordinary temperature through an antiscorbutic solution (of lime juice) inactivated it. On the other hand, on boiling an active solution for two hours in an atmosphere of CO_2, no marked diminution in the activity could be recorded, whilst on boiling a similar solution for one hour during which time air was bubbled through, almost the entire activity was lost. . . . . . .
>
> From the administration of daily doses of 1·5 c.cm., 4 c.cm., and 6 c.cm. of the juice boiled in an atmosphere of CO_2 for two hours, no inactivation perceptible by our present technique could be established. It is probable that more light will be thrown on this question in the near future.

In spite of these great strides, and the data now available, it must be admitted that the knowledge of the subject is still very incomplete, both as to the pathogenesis and exact nature of scurvy, and as to the factors influencing the vitamin. Moreover, the matter (in its modern aspect) is so much in its infancy that it has not been possible to apply the test of time even to the extent of the few years during which an expedition is cut off from supplies.

Pathology of Scurvy.

The pathology of scurvy, in so far as the results of autopsies are concerned, has been known for many years and carefully described by independent observers, but the pathogenesis is still incomplete, and investigation in this direction is a matter of extreme difficulty. The path, however, has been broken, and much new light has been thrown on the subject by the work of McCarrison, recently embodied in a single volume.[1] It has been shown that there is a definite pre-scorbutic stage, characterised by a general depressed vitality, which persists for a varying period before the second stage, the stage of toxæmia, sets in, producing the symptoms more usually considered as characteristic of scurvy. The symptoms of the first stage are a feeling of unusual tiredness and lack of interest in things generally, a greater readiness to take to bed, and a greater reluctance to get up. There is shortness of breath on exertion, and the patient suffers from frequent headache and vague "rheumatic pains." The pulse-rate is increased, and Hess has noticed in children a tachycardia similar to that of exophthalmic goitre. Clinical observers have noticed a dilatation of the right side of the heart, though there is generally some shrinkage in that organ as a whole. From clinical observations made in Russia, where one of us had the opportunity of seeing a very large number of cases occurring in adult men, it appears that this stage may persist for a considerable period, weeks or even months elapsing before more marked symptoms arise. McCarrison describes during this period "a state of ill-health of the bowel" with "congestive and hæmorrhagic lesions in the tract." The second stage, which is one of a profound toxæmia, produces, in more or less marked degree, the symptoms of profound depression, dull earthy complexion, bleeding, swollen gums, and other conditions more usually associated with scurvy, and in the advanced stage producing the ugliest of clinical pictures. Of this condition the Austrian, Kramer, wrote, "The scurvy is the most loathsome disease in nature," and the Canadian poet, Service, forcibly, if somewhat crudely, writes:—

"... . the scurvy softens your bones
And your flesh dents in like putty, and you spit out
your teeth like stones."

The depressing effect of an outbreak of this disease during an expedition can be imagined. In the large series of cases seen by us in Russia the swelling and sponginess of the gums was a very characteristic but not altogether a constant feature; we saw some very advanced cases with pronounced symptoms in which the gums were not swollen, though bleeding occurred readily. In these cases the teeth, though loosened in the sockets, were in excellent condition, with absence of caries, which points to a probable relationship between the two conditions. The toxæmia, which is accompanied by severe metabolic disturbance, is almost certainly gastro-intestinal in origin, and in connexion with this the following extracts, having a direct bearing on the subject, are made from Robert McCarrison's "Studies in Deficiency Disease."

For the sake of brevity in this article, the wording has in places been considerably altered:—

1. The health of the gastro-intestinal tract is dependent on an adequate provision of accessory food factors, especially vitamines B and C. . . . . Vitamine C . . . . is especially concerned in the production of congestive and hæmorrhagic lesions in the tract, and evidences of these may be found in animals which have not exhibited during life any clinical manifestation of scurvy in a noteworthy degree. A state of ill-health of the gastro-intestinal tract may thus be a pre-scorbutic manifestation of disease due to insufficient vitamine intake. . . . .
2. The disorder of the intestinal tract is enhanced when the deficient food is ill-balanced.
3. In general the disorders resulting in this situation from deficient foods are:—(*a*) Congestive, necrotic, and inflammatory changes in the mucous membrane, either involving the entire tract or limited to certain areas; (*b*) degenerative changes in the neuro-muscular mechanism, tending to dilatation of the stomach, ballooning of areas of small and large bowel, and probably also to intussusception; (*c*) degenerative changes in the secretory glands, such as must cause grave derangement of digestive and assimilative processes; (*d*) toxic absorption from the diseased bowel; (*e*) impairment of the protective resources of the mucosa against infecting agents, resulting not only in infection of the mucous membrane itself, but permitting of passage into the blood stream of micro-organisms from the bowel.
4. There is a definite individual idiosyncrasy.

Of the deleterious effects of food deficiencies on the endocrine glands, and the consequent disturbance of metabolism, we have said nothing, though their importance in the pathogenesis of scurvy is fully recognised. The exact processes which take place in this connexion are not clear, and for our present purpose we do not see that we can draw any practical conclusion from the present-day knowledge of the subject. The changes in these glands do not seem to result from the bowel lesions, but have a certain amount of influence on their production. McCarrison says: "Whatever be the true nature of vitamines, they resemble in their action that of hormones, whose function is to stimulate metabolism." He shows that some of the endocrine extracts "can delay in onset, and alleviate, though not permanently dispel, the symptoms of polyneuritis in pigeons suffering from deprivation of vitamine B." Extracts of the thyroid, or of some of the other endocrine glands, might therefore be of use in staving off the more pronounced effects of scurvy, and in this way might be of real value on a sledging journey which had resolved itself into a race against time, and where the ability to carry on for a few days more would bring the party within reach of a depôt of supplies, as occurred in the case of the late Captain Scott and his companions; though we do not know that scurvy was the cause of death on that occasion.

For many years certain factors have been regarded as having a predisposing influence: cold, fatigue, mental depression, fear, short rations, crowded, dirty, and ill-ventilated surroundings, and individual idiosyncrasy.

In passing we must remark that this analysis of the situation does not in any way pretend to be a complete epitome or representation of the present-day knowledge of scurvy; we have attempted merely to pick out those considerations which we regard as being of practical value, to be carefully weighed as having a direct bearing under the heading of this article.

Factors Bearing on Incidence of Scurvy in Polar Expeditions.

Further, fully to understand the problem it is necessary at this stage to explain the circumstances in respect of the incidence of scurvy which may arise during a Polar expedition. Life on the ship, or at a well-stocked base, permits of a full and varied diet, and more or less bulky foods can be carried. Accommodation is, of course, very limited, but quarters can be kept in their work each to his respective institution; instead of which they should be regarded as public officials whose specialist services should be freely available at all centres in their locality where either mental treatment or the diagnosis of mental condition is required as part of the public's medical and allied services. In short, fluidity of service should be brought about, which in most instances will need not legislation, but an alteration in the institution's rules, which are so far statutory that, having received the Secretary of State's (now the Minister of Health's) approval, they have the force of law. This fluidity of service would enable much preventive and early treatment, now neglected, to be performed, nor would that be at the expense of the medical staff's institutional duties; on the contrary, the constant touch kept with the periphery, the witness of the operation of predisposing factors, and the better knowledge of premonitory symptoms and early stages of mental disorders, would broaden the outlook of the medical staffs, and much enhance their effectiveness within the institution.

Fluidity of service is required, not only for routine therapeutic work at clinics and in out-patient departments of general and other hospitals, but also for work in at least two of four other important relationships which psychological medicine ought to establish. These four are its relations (i.) to medical services for school children—details of which will be supplied in a paper from Dr. G. A. Auden, (ii.) to criminology—the valuable work being carried out at H.M. Prison at Birmingham may be cited as an example, (iii.) to industrial hygiene—concerning which an account will be contributed later by Dr. C. S. Myers, and (iv.) to the naval and military medical services; and it is as regards the first two that this fluidity of service is chiefly required.

As ancillary to these matters, allusion may be made to health visitors, the value of whose services in relation to mental treatment is insufficiently realised in this country. They are at present only represented, as respects psychological medicine, in connexion with the work of the Mental After-Care Association, and with that of the Central Association for the Care of the Mentally Defective. They should be recognised as indispensable throughout the whole of the scheme of work that has been outlined, and our public mental institutions could do much in promoting arrangements for the training of suitable persons.

In conclusion, Dr. Bond added: But for the obvious utility of specific reference to, and falling in line with, the Consultative Council's scheme, my address might perhaps better have taken "Mental Hygiene" as its title; for, indeed, such suggestions as I have been able to offer have as their ultimate goal the promotion and preservation of mental health. Even should all these proposals mature, pruned and added to as none better than the Medico-Psychological Association is capable of doing, all the work requisite for this preservation will not be overtaken. It is therefore of good augury that an idea is afloat to establish in this country a National Committee for Mental Hygiene on the lines of the body of men and women who, under that name, have been for the past 13 years doing such magnificent work in the United States, and out of whose example similar committees have sprung up in the Dominion of Canada and are contemplated elsewhere in the Dominions and in France.

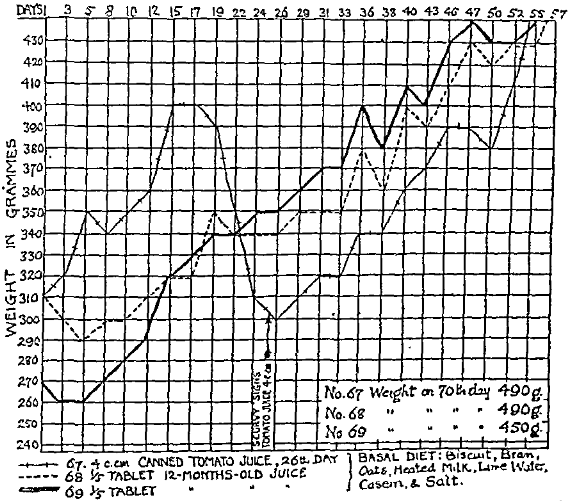
FURTHER EXPERIMENTS ON THE PRESERVATION OF LEMON JUICE AND PREVENTION OF SCURVY.

BY SIR PERCY W. BASSETT-SMITH, K.C.B., C.M.G., F.R.C.P. LOND., F.R.C.S. ENG.,
SURGEON-REAR-ADMIRAL, R.N.

IN previous papers[1] I have drawn attention to a method of making a portable, palatable, and efficient dried preparation of lemon juice, which it was hoped would be particularly useful for landing parties in special expeditions of naval character, or, more particularly, for sledging work in arctic and antarctic regions. It was, however, necessary to test these tablet forms after prolonged periods of storage, for the time element is generally recognised as being one of very great importance in reducing the antiscorbutic value of most preparations.

I have therefore tested healthy young guinea-pigs of about 300 g. weight with tablets which had been stored in the laboratory at room temperature for over 12 months. The basal diet consisted of ships' biscuit, bran, oats, casein, salt, and lime-water, with 60 c.cm. daily of milk so heated as to destroy any antiscorbutic vitamin. Each day one-fifth of a tablet was given, equivalent to 4 c.cm. of fresh lemon juice. The animals under experiment have over a period of 70 days showed no signs of scurvy; they are bright and healthy and have steadily gained weight, as shown by the curves in the annexed chart. Control animals, without antiscorbutic factors, show signs of scurvy about the 21st day and then rapidly lose weight (Chart 1).

CHART 1.



It has been previously shown that short periods of heating, even at boiling point, only slightly reduce the antiscorbutic value of lemon juice, and it is probable that these tablets could be produced on a commercial scale by a process similar to that used for the preparation of Nestlé's condensed sweetened milk, which contains most of the original vitamins[2]; the milk is heated for about three and a half minutes close relationship between this and other deficiency diseases, especially beri-beri. In so far as they can be separated clinically, however, the latter presents for its prevention a much less difficult problem. The anti-beri-beri (anti-neuritic or water-soluble B) vitamin is much more resistant to extraneous factors than the anti-scurvy vitamin, and foods in which it maintains its activity are more easily obtainable. Its elimination is aimed at on the ship by provision of the following foods: rice (containing germ), whole meal flour, dried eggs, dried peas, beans and lentils, fresh meat (including the sweetbreads, liver, and brains of any animals killed), and marmite is added to the sledging ration, which in itself probably contains active anti-beri-beri vitamin. During the course of the expedition fresh penguin eggs will be freely used if obtainable.

[2] Hume, E. M.: Bio-Chem. Jour., 1921, vol. xv., No 1, pp. 163–166.

It is probable that the next few years will show great advances in the knowledge of deficiency diseases, and in Admiral Bassett-Smith's work in connexion with prophylaxis in the Navy a ready-made system will be available for future exploration.

In conclusion, we wish to thank many prominent workers who have given us their ready assistance in our preparation, Admiral Bassett-Smith, and Dr. Hess, of New York, for personal interviews and much sound advice; Surgeon-Commander E. L. Atkinson, Dr. G. de M. Rudolf, and others. We have made full use of all available literature, and our acknowledgments are due to the various authors.

ANÆSTHESIA WITH NITROUS OXIDE AND OXYGEN UNDER PRESSURE.

BY H. H. DALE, M.D. CAMB., F.R.S.,

AND

LEONARD HILL, M.B. LOND., F.R.S.

(*From the National Institute for Medical Research, Hampstead.*)

DURING recent years it has come to be recognised that nitrous oxide, mixed with sufficient oxygen to make it respirable over a long period, is the safest and most physiological of all anæsthetics, its use being unaccompanied by unpleasant or dangerous accessory effects either during or after the operation.

When shock is threatened, or when a definite toxæmia is present, chloroform or ether accentuates the danger, whereas nitrous oxide with oxygen seems to be harmless in this direction. The fact that histamine produces fatal shock in an animal which has been long under ether, in doses harmless to a normal animal, or to one anæsthetised with nitrous oxide and oxygen, was recently shown experimentally by one of us (H. H. D.).[1]

On the other hand, the use of nitrous oxide and oxygen has the drawback that, when sufficient oxygen is given to secure perfect oxygenation of the blood, the anæsthesia obtained is not deep. It is notoriously difficult under such conditions to obtain an adequate relaxation of the belly wall for an abdominal operation, unless the muscles are paralysed by nerve-blocking with a local anæsthetic in addition. To secure deep anæsthesia, with full relaxation, by means of N_2O, the proportion of oxygen must usually be so reduced that the patient is slightly blue; the anæsthetic effect is complicated by a partial asphyxia. When pure N_2O is used for short operations, as in dentistry, the asphyxial element becomes very prominent, the anæsthesia produced being largely due to asphyxia, and not differing greatly from that which is produced by inhaling pure nitrogen until unconsciousness occurs.

At present, therefore, anæsthesia with nitrous oxide and oxygen is apt to be a compromise between the disadvantages of imperfect relaxation and those of exposing the patient to defective oxygenation of his blood. These latter are likely to be more serious in the case of a patient for whom nitrous oxide and oxygen on other grounds would be the anæsthetic clearly indicated, by the presence of toxæmia. Dr. Otto Leyton called to the attention of one of us (L. H.) the need of an anæsthetic for use on diabetics, free from these alternative drawbacks, and recalled the demonstration made long ago by Paul Bert, of the possibility of maintaining deep anæsthesia by means of a mixture of nitrous oxide and oxygen in a chamber under a small positive pressure.

Experiments on Dogs.

As long ago as 1878,[2] Bert observed that complete relaxation could be produced in a dog by putting it in a pressure chamber filled with a mixture of N_2O and O_2, 5 parts to 1, under a plus pressure of one-sixth atmosphere. The corneal reflex was abolished, pinching an exposed sensory nerve caused no reaction. A limb could be amputated without any movement on the part of the animal. Recovery from the anæsthesia took place after three or four breaths of pure air. Martin[3] studied continuous anæsthesia produced by this method. He filled a bell-jar with a mixture of N_2O and O_2, 85 parts to 15, and raised the pressure as Bert had done. A flow of the gaseous mixture was adjusted to ventilate the chamber, and, in addition, some milk of lime was put within to absorb CO_2. An animal within this bell-jar was thus kept anæsthetised for 72 hours. On withdrawal it began to move after 15 minutes, tried to stand up after 35 minutes, walked and obeyed commands after 55 minutes, but refused milk. Next morning it appeared normal and ate food eagerly.

Bert[4] states that pressure chambers for performing surgical operations under his method of anæsthesia were being installed at the Hospital St. Louis at Paris, also at Lyons, Geneva, and some towns in Germany.

We could find no published records of the use of these chambers, but merely the statement, in a recent text-book, that they had not succeeded, and that one of them was to be seen still, as a curiosity. Through the courtesy of the present Superintendent of the St. Louis Hospital we received the information that alarm at a mishap occurring when the chamber was first used, which nearly resulted in the death of the patient, had led to the abandonment of the method. Whatever the accident might have been, it seemed clear that it could not be due to anything inherent in the method, and, in view of the practical interest of the matter, we decided to make the experiment on animals, under conditions which, with small modifications, could be applied to a surgical operation on man, if a suitable chamber were available.

Experiments on Cats.

The animals used were cats, and they provided rather a severe test of the method, on account of the difficulty of producing a really deep anæsthesia in the cat, without reducing the oxygen in the mixture to a point near to the limit compatible with life. The mixture of N_2O and O_2 was made in a large Douglas bag and passed through a meter to a mask which snugly fitted the snout. When we used 4 parts N_2O to 1 part O_2, and a current through the mask of 4 litres per minute, the animals continued to wag their tails, to breathe noisily, and to show rigidity of the adominal wall and resistance of the legs to passive flexion. When the ventilation was reduced to 2 litres and then to 1½ litres per minute, the animals were a little more deeply anæsthetised, but still too lightly to stand any operative measure. The pads were moist and pink in colour. When the mask was removed after inhalation had lasted for 30 minutes, the cats were able to walk when put to the ground, but were slightly ataxic for a few seconds. Cats are known to be particularly resistant to N_2O, so we next tried a mixture of 1 part O_2 to 7 of N_2O. With a ventilation of 3½ litres per minute the limbs and literature dealing with the subject was extremely meagre, much of it in foreign languages, and available only to those with access to large and well-stocked medical libraries. Little attempt was made to keep it up to date. Reference to the history of Polar exploration, and the records of early voyages of discovery, showed that reports in connexion with antiscorbutics, though often dogmatically made, were unreliable, and contradictory results were obtained from apparently similar methods of prevention. The number of possible fallacies in deductions drawn and the probable influence of unconsidered factors, showed that no real assistance could be drawn from this source. Certainly the value of fresh foods, especially fruits and vegetables, had long been recognised, as is seen by the memoirs of the famous Captain Cook, who made use of them on every available occasion, and whose voyages were remarkable for the absence of scurvy in the advanced stage; for in those times the disease was frequently not recognised until it had reached an advanced stage. The improved conditions resulting from Board of Trade regulations in connexion with seamen showed a marked diminution in the number of cases occurring at sea; and this diminution was largely attributed to the use of lime juice, which for many years held sway as a sure preventive of scurvy, and a certain cure for it when it had set in.

Method Adopted by Sir E. Shackleton.

In 1913–14, when the last expedition was in process of preparation, a reliable system of prevention was particularly difficult to form, for lime juice had been shown to be of doubtful value, and the "vitamin theory," though established, was still in its infancy; and of the factors influencing the vitamin comparatively little was known. It had not been shown that the Mediterranean lemon possessed a much greater antiscorbutic value than West India lime; the failure of lime juice was attributed to the high temperature used in its concentration. Nevertheless, Sir Ernest Shackleton, who fully realised the importance of strong anti-scurvy measures, and who had made himself fully cognisant with the state of knowledge at that time, took every possible step to secure them, relying not on any one preparation, but on providing a well-balanced dietary. How far the method was effective in this respect the results of recent workers, especially McCarrison,[1] have shown, and all Sir E. Shackleton's expeditions have been remarkable for the absence of any signs of scurvy. The system adopted lay in the provision on the ship of good foods, supplied in great variety and in ample quantity, great care being taken to see that it was served cleanly, and in as attractive a manner as conditions permitted. Living quarters were made as bright as possible and kept scrupulously clean. Everything possible was done to maintain general good health and a high morale. For sledge journeys a preparation of lime juice was made in the concentration of which low degrees of heat were used, and the product was put up in air-tight capsules, each capsule containing a ration for one day. In the light of more recent knowledge this ration was probably not rich in active vitamin, but its efficacy was never tested, for no extended sledge journeys were carried out until after the loss of the *Endurance*. For 10½ months the party lived on a severely restricted and monotonous dietary, but it was composed largely of fresh meat.

Epitome of Results with Different Antiscorbutics.

Between that time and the present, however, a great deal of work has been done, and great advances have been made both along the lines of clinical investigation and direct experiments on animals.

An epitome of the results having a practical application is here given:—

Lemon Juice.—The historical investigations of Chick, Hume, and Skelton[2] and of A. H. Smith,[3] followed by experiments on animals at the Lister Institute by Chick and Hume, have displaced lime juice from its time-honoured position as an antiscorbutic, but have shown that lemon juice is very rich in active vitamins and has in the fresh state a high antiscorbutic value. It withstands drying under certain conditions. Holst and Frolich pointed out that by evaporating fresh juice in a vacuum the efficacy was retained, and Harden and Zilva that by drying it in an acid medium an active residue is left. Admiral Bassett-Smith[3] has elaborated these methods, and with a view to prophylaxis in the Navy has prepared a convenient and portable product by evaporating the juice in vacuo over sulphuric acid; a viscid syrupy mass is left which may be preserved by the addition of 10 per cent. alcohol—which also prevents freezing—or by making it into tablets. In both forms it has been shown to retain its antiscorbutic value. There has not yet been time to test fully its keeping qualities over a number of years, but there is no doubt that these preparations will be of the utmost value in Polar exploration, and in other circumstances where similar conditions are met with. The amount estimated as necessary per man per day for prophylaxis is the equivalent of half a lemon in the fresh state.

Orange Juice.—Orange juice has also been shown to have high antiscorbutic value, and Givens has prepared a dried product, containing active vitamin, which has retained its efficacy after two years' storage.

Milk.—Chick, Hume, and Skelton have shown that milk in the fresh state has a comparatively low antiscorbutic value which varies according to whether the cows from which it was obtained were fed on fresh greenstuffs or not. Milk powder, however, may be comparatively rich in vitamins, but this depends largely on the manufacturing process to which it has been subjected.[4] The "spray" process of drying milk has been shown to be very detrimental to the antiscorbutic vitamin, but the "roller" process is much less so. Milk prepared by the Just-Hatmaker process has been shown by Hess and Unger[5] to be efficacious, both for the prevention and treatment of infantile scurvy. In this it is poured in its fresh state on to two revolving drums, heated to a temperature of over 100° C., on which it forms a film, and is scraped off within a few seconds by a knife edge into a container. Other factors essential to a good powdered milk are good pasturage, healthy cows, hygienic methods of dealing with the milk, and as little exposure to air as possible during the whole process.

Vegetables.—Most fresh vegetables are richly antiscorbutic, but dried vegetables have been shown to be almost totally devoid of active vitamin. Holst and Frolich, however, have prepared an active dry preparation of white cabbage by keeping out all moisture and preventing hydrolysis, but evidence in connexion with it is scarce. Vegetables preserved in tins by the process of canning are also of little value. A notable exception is canned tomatoes, which Hess and Unger have shown to be antiscorbutic, and have used it with success in infantile scurvy. It has also been adopted for use in the United States Army. Campbell and Sherman state that after boiling for one hour, tomato juice loses only 50 per cent. of its water-soluble C vitamin, and about 70 per cent. after four hours. The rate of loss is increased if the juice be first made alkaline or neutral.

Germinated Pulses and Cereals.—Furst was the first to demonstrate the presence of active vitamin in germinating cereals. Chick, Hume and Delf at the Lister Institute have carried on further investigation, and the result is one of importance in Polar exploration, for the dried pulses and cereals can be easily carried and made to germinate as the occasion requires. Wiltshire applied this treatment clinically in dealing with an outbreak of scurvy amongst Serbian soldiers, and he describes it as being superior in value to treatment by lemon juice.

Meat.—Preserved meats may be regarded as having no antiscorbutic value at all. Dietcher, Pierson, Biester, and others found that small amounts of fresh beef had no appreciable effect in the prevention of scurvy. There are numerous instances, however, in the history of exploration, which show that fresh meat is able both to prevent and to cure scurvy, provided enough of it be eaten. It has been suggested that it must be eaten raw or lightly cooked, but our own experiences in the last Shackleton expedition showed that this is not necessary.

Factors Influencing the Vitamins.

The anti-scurvy or water-soluble C vitamin has been shown to be more sensitive to destructive influences than either the fat-soluble A, or water-soluble B vitamins. The influences most detrimental to its activity have been considered to be heat, drying, exposure to air, ageing, and an alkaline reaction. The precise factor acting on the vitamin has not been clearly shown. With regard to heat, the experiments of Miss Delf tended to show that intensity of heat is less destructive than prolonged heating at a lower temperature. Results, however, proved puzzling, and a more recent experiment by Zilva, carried out at the Lister Institute, shows that probably an undue

The major period involves the first third of the gestation period, and the minor is a diurnal periodicity. Sometimes, but very rarely, the nausea and vomiting extend beyond the third or beginning of the fourth month. Many cases which have been most distressing in their symptoms clear up spontaneously at about this time, and many women, knowing this, acquiesce in the discomfort and distress of their condition instead of seeking relief at experienced hands. In this they have been encouraged, either openly or tacitly, by the inability of the medical profession to aid them in their difficulty, and such an attitude has confirmed their belief that a certain degree of nausea or even vomiting is an inevitable accompaniment of child-bearing.

Minor or Diurnal Periodicity.

The minor periodicity of nausea and vomiting in pregnancy is shown clearly by the use of the designation "morning sickness," though all cases do not exhibit this periodicity in the morning. Nevertheless such a periodicity is very common, and a diurnal wave of nausea is often observed even if the crest is not matutinal. Such intermittent cases pass insensibly into a continuous condition of nausea or vomiting. The rejection of food, both involuntary and voluntary, with the supervening starvation, intensifies and complicates the picture until we come to know it as pernicious vomiting. It is evident from the latter statement that the so-called pernicious vomiting is regarded as a development of the milder form, differing only in degree, and in multiplicity of effects. Indeed, the work on this subject was commenced with the idea of separating the factors involved in pernicious vomiting through a study of its presumably simpler forms.

Findings Relating to High Carbohydrate Diet.

The following facts had had a determining effect on the choice to attack the problem experimentally through an investigation into the effect of high carbohydrate diet on the simpler cases of vomiting in pregnancy.

(*a*) Autopsy findings, in a large number of cases in the literature, of acute yellow atrophy of the liver.[7] The necrosis of the central portions of the lobules and the fatty degeneration of the peripheral portions occur, even in so-called acute cases where marked emaciation of the patient is not shown.

(*b*) The findings of Mottram[8,9] that a short period of hunger was sufficient in some animals to produce a fatty infiltration of the liver, and that a similar condition was sometimes found in ill-nourished and nervous pregnant animals. These fatty infiltrations are purely physiological in character and readily pass away under more normal conditions.

(*c*) The knowledge that of all metabolic disturbances the carbohydrate metabolism is the one most readily affected.

It is easy to see that, given the above-mentioned facts, a connexion could readily be traced between a disturbance of carbohydrate metabolism, resulting from a disturbance of the glycogen of the maternal liver, upon which a fatty infiltration would ensue, and the autopsy findings, in the advanced cases of vomiting, of extensive hepatic degeneration. If there existed any parallel between the animal experimentation of Mottram and the human cases, then pregnancy, together with a short period of hunger, was sufficient to account for the minor periodicity of the nausea and vomiting of pregnancy.

Starvation and Nausea.

In this connexion Dorman [10] makes the statement:

> "Small amounts of easily digested food are to be taken every two or three hours, with regular meals omitted. Many patients discover this fact for themselves. *The extremes of nausea come on after a prolonged fast.*† Sometimes the evening meal, which is a late dinner, following a light luncheon, is the time of greatest distress. The meal is approached with a great distaste for food and is either refused or rejected after eating. The underfeeding then exaggerates the nausea. A tolerance for dinner may be acquired by taking afternoon tea."

Titus, Hofmann, and Givens,[6] commenting on morning sickness, remark:

> "The first nausea of pregnancy usually affects the patient early each day soon after she arises. *This is after the longest period of fasting in the 24 hours.*† An overnight fast can produce only moderate hunger, but any hunger may be considered mild starvation. If eating before making any exertion relieves this morning nausea it is obvious that there is a relation between starvation and the occurrence of the nausea."

One of the first characteristics of starvation is a lowering of the glycogen content of the liver. With prolonged starvation it may disappear entirely. Fatty infiltration of the liver is an inevitable sequel to glycogen diminution, and the logical procedure to avoid such a condition is to maintain the glycogen content at as high a level as possible. In this way the treatment of nausea and vomiting in pregnancy by the use of a high carbohydrate diet was devised, with the results which were mentioned at the beginning of the paper. Moreover, the possibility of failure of normal protein metabolism, which had been advanced by Stone [11] and by Ewing and Wolf [12] had been entirely discredited by the damaging criticism of Underhill and Rand [13] and the precise experimental findings of Losée and van Slyke.[14]

In connexion with the influence of starvation Titus, Hofmann, and Givens have unjustly criticised the theory of our previous paper, although as has just been quoted, they themselves point it out as a factor in the condition. In fact, if the two papers are compared side by side they present a wonderful similarity. A short period of starvation lowers the glycogen content of the liver. This short period during the night hours is ordinarily insufficient to produce any symptoms, but in pregnancy there is added an extra strain upon the glycogen supply due to the pregnant condition itself. It is thus the double load upon the maternal liver which is sufficient to produce a temporary fatty infiltration of the organ, which clears up during the day hours under the influence of the carbohydrate of the food. The evidence of the fatty infiltration, or even perhaps of a slight degree of fatty degeneration, is shown by the occurrence of acetonuria even in very mild cases of nausea and vomiting. Small areas of fatty degenerated liver are known to become normal under carbohydrate feeding,[15] though the beautiful work of Whipple and his associates [16] only appeared after the publication of our first paper. The clinical use of glucose in cases of delayed chloroform poisoning is also well known.[17] On the other hand, one portion of the theory advanced by us is certainly open to criticism. At the time we had before us a personal communication from Imrie to Mottram[18] stating that the fœtus was greedy of unsaturated fat. Since then Imrie [19] has published his results in full, and it is evident that the statement referred to fat in the fœtal liver at term. Such results, of course, could have no bearing on the present discussion, and any arguments previously based on them must be withdrawn.

Major Periodicity.

The minor periodicity of nausea and vomiting thus receives adequate explanation on a theory of glycogenic disturbance, or carbohydrate deficiency, in the maternal liver. The major periodicity also is capable of interpretation by this hypothesis. The first third of pregnancy is characterised by the parasitic behaviour of the fertilised ovum, and the defensive measure adopted by the mother in the formation of a placenta, with the subsequent change of the parasitic life to a symbiotic one. Accompanying this is a period of nitrogen loss, in many experimental animals,[20] and although a similar negative balance has not been observed in women it is extremely likely that such is the case.[21] Both Bar [20] and Murlin [20] have pointed out the coincidence of this negative balance of nitrogen and what they term "physiological vomiting of pregnancy." Both terminate of themselves at about the same time. Placenta formation is also complete at about the same period, and it is warm, airy, clean, and bright, and if the personnel has been carefully selected, there is no reason why morale should be low. The conditions on a sledge journey are not so good, and, as far as the danger of scurvy is concerned, vary considerably in the methods adopted. There are explorers who advocate the close copying of methods adopted by the Eskimo, and depending for subsistence largely on such "game" as these barren areas afford. This necessitates a very large consumption of fresh meat, and experience shows a great freedom from scurvy under these conditions. However, there are obvious disadvantages in such a method of travel; the activities of the party are limited to "game" areas, and the daily rate of progress is necessarily very slow. It is quite inapplicable to the dead, gameless Antarctic continent, and under any conditions where the total distance to be covered is great, where the areas to be crossed are totally unknown, possibly devoid of all sources of food, and where rapidity of travel is essential. Under these conditions all food must be carried, it must of necessity be light, and to meet the large expenditure of body energy each ration must have a high calorific value. To obtain the necessary lightness all excess of moisture must be driven off, and the manufacturing processes necessary are such that at present no reliance can be placed on them for the supply of antiscorbutic vitamins.

---

† The italics are mine.—V. J. H.

The modern sledging ration allows of approximately 2½ lb. of food per man per day on full rations, but circumstances may necessitate a reduction of this amount, and cold and fatigue are certain to be more or less constant factors at some stage of the journey. In this type of sledging occasions sometimes arise in which the route leads through a "game" district, and of course full advantage is taken of any opportunity to procure fresh meat. These occasions, however, cannot be relied on, and so the deficiency of vitamin in the sledging ration must be made up by the addition of foods containing sufficient active vitamin to maintain health. In Polar exploration, even when extended sledge journeys are not contemplated, the physical forces of the area are such that unforeseen events may happen, leading to circumstances in which the supply of food may be small and unvaried. Such possibilities, with the danger of the supervention of scurvy, must be considered beforehand, and preparation made for them. They may be classed for practical purposes under the heading of "sledging conditions."

Prevention of Scurvy.

On the above considerations a system for the prevention of scurvy falls naturally under three main headings: (1) the elimination of predisposing factors; (2) the supply of active antiscorbutic vitamins in sufficient quantity; (3) careful treatment of the bowel in the pre-scorbutic stage, and the elimination of extraneous toxins from the gastro-intestinal tract.

It must be directed also to the two sets of conditions outlined above: (1) life on board ship or at a well supplied base; (2) sledging conditions, including abnormal circumstances arising from accident.

The elimination of predisposing conditions is aimed at, in the manner previously indicated, by good management of living conditions in general and maintaining a high morale. The former has been an outstanding feature of all Sir E. Shackleton's expeditions, and with regard to the latter it is interesting to note that in writing of the characteristics necessary to an explorer he has placed the quality of "optimism" high above that of "muscular strength," though sound health and fitness of the personnel are, of course, a sine quâ non. The hours of relaxation are carefully provided for, music is supplied by gramophone, and a large and well-selected library is carried. The most important part of the system depends upon the correct balancing of the dietary and in the selection of foods calculated to contain the active vitamins in sufficient quantity. In carrying this out it is necessary not only carefully to select the foods but to ensure the packing so that at the time of consumption the vitamin shall not have been impaired by age or exposure. The main principles involved in attaining this are: (1) quick packing immediately after preparation, avoiding undue exposure to air; (2) rigid exclusion of the products from air by using hermetically sealed containers; and (3) the storage of cases containing antiscorbutic foods in a cool place, avoiding proximity to engines or boilers.

Reliance has been placed on the following foods:—

On Board Ship.—Lemon juice concentrated by the method advocated by Admiral Bassett-Smith, but not made into tablets, the concentrated juice being treated by the addition of 10 per cent. alcohol to prevent its freezing. Dried milk. Considerable reliance is being placed on the regular daily consumption of dried milk. We have been to great pains to see that the preparation carried has been prepared from healthy cows fed on good pasturage, subjected to as little handling as possible, and prepared by the "roller" process, whereby the milk is subjected on drums to a high temperature for a few moments only. In the packing of it care has been taken to see that at no stage shall it be exposed to undue oxygenation, and similar care will be used when the milk is issued and served. Condensed milk is also being used. Fresh meat will be used whenever obtainable. The meat of the various seals, whale meat, and penguin meat, though having an oily taste, can be made quite palatable by careful cooking. Canned tomatoes will be issued regularly on board ship. As regards germinated pulses and cereals, a quantity of peas, beans, and lentils will be carried, and in the event of signs of incipient scurvy appearing will be used after having been made to germinate. It is necessary to serve them lightly cooked, and as they are very indigestible, they will not be used for prophylaxis or until the necessity arises. Whenever any opportunity occurs of obtaining supplies of fresh vegetables full advantage will be taken of it. In addition a supply of potatoes, carrots, and onions will be carried, and their use prolonged as far as conditions permit.

Sledging Conditions.—Lemon juice tablets, as advocated by Admiral Bassett-Smith, packed in air-tight containers. Dried milk, as above, packed in small air-tight packages, each package containing only one day's ration, thus avoiding undue exposure to air. For the supply of fresh meat a rifle and shot-gun and ammunition form part of the equipment of each self-contained unit in any area where "game" is obtainable.

A representative modern daily sledging ration is composed as follows: pemmican, nut food, biscuit, tea, sugar, dried milk, amounting to a total weight of about 2½ lb. per man per day, and having a food value of about 5000 calories. None of these foods can be relied upon to prevent the onset of scurvy; hence the importance of carrying a reliable antiscorbutic preparation.

The elimination of gastro-intestinal toxæmia is aimed at primarily by supplying a well-balanced ration and sufficient food containing active vitamin, as outlined above. Great care will be taken to maintain in each member an orderly condition of the bowels. Constipation is a factor which frequently arises in Polar expeditions and is due to two main causes: the first is that whereas on the whole every member of the expedition leads a vigorous, active life, occasions occur in which for considerable periods no exercise at all can be taken. Also the process of defæcation has often to be carried out under most unpleasant conditions, when the individual makes the period of exposure as short as possible, tending to incomplete evacuation at each act. A careful preliminary examination will be made, also, of the personnel, especially of the mouth and nasal passages, to avoid any potential sources of toxins, such as dental caries, pyorrhœa alveolaris, chronic rhinitis, or latent chronic disease of the nasal accessory sinuses.

Poisoning from outside the body will be as far as possible eliminated by careful attention to tinned and potted foods, and also by rigidly rejecting the meat of any locally killed animal which shows signs of disease. We found on the last expedition that diseased conditions producing marked pathological changes occurred fairly frequently among seals and penguins.

Conclusion.

In this article attention has been particularly directed towards scurvy and the anti-scurvy or water-soluble C vitamin, but it is realised that there is a and the practical applications certainly merit consideration and trial. It may, however, rightly be asked if there is no other condition in which an analogous state of affairs exists? A very analogous condition sometimes arises in starvation treatment of diabetes, expecially if carried out according to the original directions of Allen,[30] where there is a complete and rapid withdrawal of food.

> "What is seen clinically is first a vague malaise, often with headache or pains elsewhere, dizziness and increasing prostration. Nausea seems to be invariable and the gravest stage is reached when vomiting is established. Though the condition is acidosis, the appearance is not that of typical coma. Dyspnœa may not be prominent, and the consciousness may be clear up to the last hours or minutes of life. The end comes with uncontrollable vomiting and profound and rapidly progressive weakness."

The avoidance of such a condition as that described is brought about by the adoption of Joslin's modification of the fasting treatment, where the starvation is brought about gradually, and it is this well-known clinical result that induces the belief that the speed of the depletion of the glycogen stores plays a big part in the resulting symptoms in the nausea and vomiting of pregnancy.

Practical Considerations.

From the foregoing certain practical considerations are evident. Each factor must be brought under control by proper treatment.

A. *The Metabolic Factor.*—The glycogen supply of the maternal liver must be kept as high as possible by use of a diet rich in carbohydrate. This does not mean that the necessary protein supply must be entirely withheld, except temporarily. Fats, however, may be excluded for quite long periods of time without any ensuing harm. A high carbohydrate diet is best accomplished in a series of small meals, five or even six in number being taken throughout the day. Cereals in various forms (bread, toast, crackers, rusks, the different varieties of breakfast foods), vegetables of all kinds, both cooked and fresh, and especially in the form of salads (without dressing), fruits both fresh and stewed, with a little milk (not cream), form a very satisfactory and appetising diet, which is rich in carbohydrate. Such a diet taken in a number of small meals for three or four days is very satisfactory with patients complaining of morning sickness or mild nausea. Their acetonuria soon vanishes under the dietetic treatment and the symptoms are replaced by a feeling of extreme wellbeing. Such a diet, however, must not be continued too long. There must be added to it a little more protein. Milk, eggs, fish, chicken, meat (except pork) are added. Among the fish we usually exclude salmon, mackerel, and whitefish, on account of their fat content. Butter, too, is usually kept at a minimum. There need be no fear on such a diet that fœtal growth will be retarded by lack of accessory factors. With fresh green vegetables and fresh fruits in the daily menu an ample supply of all of them is assured. In addition, and especially if it is thought that the dietetic restrictions will not be kept as rigorously as they should, one to two teaspoonfuls of milk-sugar dissolved in a cup of tea, or coffee, or glass of water, or lemonade may be ordered three times a day. The milk-sugar is practically tasteless. In the more severe cases where rest in bed and isolation are demanded, no attempt is made to feed the patient by mouth if there is any disinclination to take food. Usually in these cases the patient has no desire to eat, the tongue is coated, and the breath foul, the vomiting is severe, and is often bile-stained. sometimes occasionally flecked with blood. On the other hand. the vomitus may be perfectly clear. except for a little mucus. Epigastric pain is frequent in these cases. The urine may show a little bile: it contains large amounts of acetone bodies responding readily to the Rothera or the Gerhardt test: a trace of albumin is often found but rarely any casts: the volume in 24 hours is low and the specific gravity high. Some degree of dehydration is almost invariable in these severer cases, a parched tongue and mouth, dry lips and skin, and often an intense thirst mark a degree of anhydræmia. Advantage is taken of any symptom of thirst to urge fluids by mouth. Water, lemonade, orangeade, ginger ale, weak tea, any liquid of such a nature that the patient fancies is not only allowed ad libitum, but urged, and two teaspoonfuls of lactose are dissolved in each glass or cup of liquid. From 50-70 ounces of fluid a day can thus be given by mouth. At the same time 6 to 8 ounces (depending upon the amount the patient can bear with a reasonable degree of comfort) of 10 per cent. glucose are given by bowel as nutrient enemata three times a day. A cleansing enema is first given in the morning. In a few cases we have given the glucose enemata by Murphy drip, and used a 20 per cent. solution of the sugar, giving two hours on and one hour off. Some patients seem to prefer this method of administration, as the amount of fluid introduced into the bowel at one time is very small. When given 6 to 8 ounces at once, even with a urethral cathether and very slowly, a certain amount of distension is unavoidable and with it usually some degree of nausea. Usually, however, the Murphy drip method of administration produces abdominal cramps, which are very painful. We have also used 10 per cent. glucose given interstitially, generally 500 c.cm. Such administrations are, however, very painful for at least 24 hours afterwards, and the fear of a second injection has sometimes a harmful effect. This harmful effect may be mitigated by using 30 gr. bromide t.i.d. in each enema for the previous and subsequent 24 hours. Half a grain of codein may also be used the night of the injection with advantage.

Where, however, the symptom of thirst cannot be taken advantage of, and no amount of urging will cause the patient to drink, in addition to the enemata just mentioned one litre of sterile 5 per cent. glucose in normal saline is given intravenously. Like all other intravenous injections it is given very slowly so as not to embarrass the action of the heart. Two or three such injections are usually sufficient, and they are never continued when the avenue of supplying water by mouth becomes available. In spite of all this some cases continue to vomit, and the more water you get into them the greater is the volume of vomitus, while the urine still remains low in volume and of high concentration. It would seem as though the vomitus had taken the place of the urine as the excretory path for water. A chemical examination of such a vomitus shows it to be mainly water, with traces of urea and salts. It contains no acetone bodies, although the blood and the urine may contain them in high concentration. If, as Gilliatt and Kennaway [29] suggest, the vomiting is "evolved as a protective mechanism, serving to rid the body of harmful substances," certainly the harmful substances must be bile or unknown substances existing in minimal amounts. It should certainly be present in cases such as we have described, where the volume of vomitus may be two or three times that of the urine, even when no water is taken by mouth. Such cases are very difficult to treat, and are best attempted by adding 25-40 gr. of bromide to each enema for two or three days. At the same time water is supplied intravenously, and a cautious use may be made of digitalis and caffeine.

Two or three days of such metabolic treatment as has been described are usually sufficient to produce an amelioration, even in very severe cases, and most of them express a desire for something to eat. A little dry toast, or a few cream crackers, with a little preserve or marmalade are given. Mashed potato and fresh fruits come early on the list of allowed foods. Then porridge or any of the breakfast cereals are admitted, and finally a free choice of vegetables. The glucose enemata are continued until the urine becomes acetone free. Then protein is allowed, chiefly chicken and fish, for three or four days. Milk soups and purée soups are also very useful here. If, however, the clinical condition is very greatly belly were not relaxed; with 2 litres, finally reduced to 1 litre per minute, the belly wall became softer, and the legs showed much less resistance to flexion or extension; tail wagging and vocal breathing ceased. The pads were sweating and slightly blue in colour. When the mask was taken off the animal staggered drunkenly, but quickly recovered. We then tried 8 parts N_2O to 1 part O_2. With a ventilation of 3 to 3½ litres per minute the breathing was slow and deep, the pads bluish and sweating, the abdomen softer, but the recti contracted in response to a touch. With 2 litres per minute asphyxial breathing occurred and the belly was soft. When the mask was removed the animals were unconscious, with blue lips and dilated pupils, but recovered quickly after a few breaths of pure air.

Results in a Pressure Chamber.

Having shown that cats cannot be deeply anæsthetised by N_2O until asphyxiation is partly induced, we next tried the same mixture—viz., 8 parts N_2O to 1 part O_2 in the pressure chamber at the Lister Institute, for the use of which we are indebted to the Director, Prof. C. J. Martin. The method of administration was exactly the same, except that we took the cats and the bag containing the mixture into the chamber, and did not begin the administration until the air pressure had been raised till it stood at plus 7 lbs.—i.e., at about 1½ atmospheres in place of 1 atmosphere. The partial pressure of N_2O was thus raised from eight-ninths to twelve-ninths of 760 mm. Hg, that is, from 675 mm. Hg to 1013 mm. Hg, and that of oxygen from one-ninth to one-and-a-half-ninths of 760 mm. Hg, that is, from 84 mm. Hg to 126 mm. Hg. The partial pressure of oxygen in pure air at sea level is one-fifth of 760 mm. Hg—i.e., 152 mm. Hg. So that the effect of the extra half atmosphere of pressure was to raise the partial pressure of N_2O notably, and, at the same time, to make that of oxygen much nearer to that in the air of the plains, and equal to that in the air of an alpine health-resort. Be it noted that the anæsthetic is given in the pressure chamber in the ordinary way; nothing is changed except the pressure of the atmosphere, which acts, of course, upon the flexible bag containing the mixture. With a ventilation of 2 litres per minute the breathing of the cats was quiet and good, and the anæsthesia was quite as deep as in the last experiment under semi-asphyxial conditions; the belly and limbs became limp, the tail-wagging ceased, and the animal made no response to stimuli, but the pads were of a bright pink colour, with no trace of blueness. We obtained full, deep anæsthesia without any deficiency of oxygenation. When the mask was taken off the animal recovered at once and appeared remarkably alert and normal.

Conclusion.

In an operating room built as a pressure chamber it should be, then, a very simple thing to secure sufficiently deep anæsthesia in man, using N_2O and O_2, 4, 5, or 6 parts to 1, with safety, and with freedom from symptoms of after-poisoning and shock. There is no difficulty in building such an operating chamber. An air-compressor would be required to keep up the pressure at the extra half atmosphere, or less, and to ventilate the chamber, and an air lock fitted with doors would be needed to allow people to pass freely in and out. Mr. R. H. Davis, of Messrs. Siebe, Gorman and Co., tells us that the engineering problem is a very simple one, for the extra pressure required is very slight.

If there is any difficulty it will be from the surgical side, on account of the interposition of the air lock between the operating chamber and the outside. Given an adequate air compressor, passage in and out through the air lock can be reduced to 30 seconds or so. We hope it may be possible soon to bring the method to practical trial.

NAUSEA AND VOMITING IN PREGNANCY.

BY VICTOR JOHN HARDING, D.Sc.,
PROFESSOR OF PATHOLOGICAL CHEMISTRY, UNIVERSITY OF TORONTO, CANADA.

A LITTLE over two years ago J. W. Duncan and the writer[1] put forward the theory that the nausea and vomiting of early pregnancy was due to a deficiency of glycogen in the maternal liver. Such a deficiency might be either absolute or relative, i.e., actually lower than normal in amount or lowered relatively to the fat requirement of the maternal and fœtal organisms. In practical support of their ideas they advanced the two following facts which, at the time, they had collected from a series of over seventy cases:—First that, with rare exceptions, the cases showed a ketonuria; even very mild cases in which considerable amounts of food were taken gave urines responding to the nitro-prusside test for aceto-acetic acid*; and secondly, that all improved and most of them very speedily recovered upon a diet or treatment high in carbohydrate, and thus designed to combat the ketosis. It must, however, be distinctly understood that we do not regard the acetone bodies as of themselves the cause of the nausea and vomiting. The acetone bodies are to be regarded as symptomatic of the disturbed state of the maternal liver. Both these facts confirmed us in the idea that the glycogen content of the maternal liver was too low for the requirements of the pregnant organism.

In the present paper it is desired to extend and amplify the contention of the previous report. A further two years' experience with the method of treatment has only offered confirmation of the ideas, and to date, nearly two hundred cases have been treated by carbohydrate feeding with but few failures. The few failures have been either cases due to deliberate and continued breaking of dietetic regulations, or cases brought in in such an advanced condition of pernicious vomiting, that it is doubtful if any treatment would have been of avail. Moreover, Titus, Hofmann, and Givens,[5] have recently published an account of carbohydrate feeding in vomiting of pregnancy which is almost identical with that of Harding and Duncan in its practical details, though they differ in some points of theoretical explanation. Their series of cases numbers over seventy, and that independently they should have arrived at similar conclusions is of itself strong evidence in favour of the theory of glycogen disturbance in the maternal liver. It is not proposed in this present paper to give any extensive review of the literature of the subject; the latter has attracted the attention of obstetricians, pathologists, and chemists to a considerable degree, and has of necessity gathered around itself a multitude of theories, many of which can only be of transitory value. Moreover, from time to time there have appeared excellent reviews in other contributions.[6]

A. *The Primary Ætiological Factor.*

In the nausea and vomiting of pregnancy there are two periods of occurrence, a major and a minor.

---

* It cannot be too strongly emphasised and reiterated that the most delicate test for aceto-acetic acid, and consequently for a ketosis, is the sodium nitro-prusside reaction, discovered in its original form by Legal[2] and believed later to be a test for acetone. Harding and Ruttan[3] were the first to point out the mistake and show that the reaction with sodium nitro-prusside and ammonia, especially in presence of strong acetic acid, should be interpreted as aceto-acetic acid, and not as acetone. They found that urines containing no acetone but containing aceto-acetic acid gave a strong positive reaction while urines containing acetone in amounts equivalent to those containing aceto-acetic acid only gave at the most a very weak coloration. They also compared the relative sensitiveness of the Gerhardt or ferric-chloride reaction with the nitro-prusside reaction. In urine the ferric-chloride test for aceto-acetic acid ceased to be positive at a concentration of one part in 7000, while the nitro-prusside reaction continued to give positive tests until the acid had diminished to a concentration of one part in 30,000. These figures refer to the concentration in urine. In water the test is from five to ten times more delicate still. Hurtley[4] has independently arrived at the same conclusion. This point has been emphasised as the significance and priority of our paper appears to have been overlooked.

on the boat she was very ill with an undiagnosed complaint, from the effects of which she was only recovering when she first attended the hospital.

From the history it was concluded that the illness from which the patient suffered on the boat must have been the original typhoid infection, and it was confidently expected that plentiful agglutinins would still be remaining in the blood. Serum was accordingly obtained and tested in dilutions of from 1/250–1/2500 against the Lister Institute agglutinable typhoid emulsion. To my great surprise no agglutination was obtained. At the same time a catheter specimen of urine was obtained and cultures were taken from the operation wound, which was now almost healed; no growth of *B. typhosus* was obtained from either source.

The absence of agglutinins from the patient's serum seemed so inexplicable under the circumstances that a further agglutination test was performed with the original organism, with the same result as before. Furthermore, one agar slope culture of the organism was used to absorb 2 c.cm. of a 1/10 dilution of the Lister Institute agglutinating serum (already diluted 1/10). The absorbed serum was then put up in dilutions of whole serum of from 1/250–1/5000, against a known agglutinable typhoid strain, when it was found that the agglutinins had been completely removed within these limits. All doubt as to the identity of the organism with *B. typhosus* was finally removed by this result, which was confirmed by Dr. H. Schütze of the Lister Institute, who very kindly typed the organism independently.

On the strength of these findings the M.O.H. of the district in which the patient lived was notified, and shortly afterwards a report was received from him that examination of the patient's fæces had resulted in the isolation of an organism shown by agglutination tests to be *B. typhosus*. Various attempts were made to get the patient to report again to the hospital, with a view to ascertaining if her serum would agglutinate her own organism, but unfortunately she had moved from London and her experiences since her identification as a typhoid carrier had not encouraged her to go out of her way to deal with medical men.

The points in this case to which attention is particularly drawn are: (1) the occurrence of a typhoid abscess in the breast, having, so far as could be made out, no association with underlying bone; (2) the fact that the patient, although a carrier, was unaware that she had ever had typhoid fever: and (3) the absence of typhoid agglutinins in the patient's own serum.

SCHISTOSOMA MANSONI IN SOUTH AFRICA.

BY F. G. CAWSTON, M.D. CANTAB.,

FIRST STREATFEILD RESEARCH SCHOLAR.

IN view of the return to Natal in 1918 of a large number of our troops from the campaign in Egypt, I drew the attention of the Defence Department to the large number of fresh-water snails in the Durban suburbs which might act as intermediary hosts for the Egyptian form of *Schistosoma mansoni*, which up to that time was unknown in South Africa except on the Rand, amongst native labourers who had been imported from the tropics.

In August, 1919, I motored Dr. Annie Porter of the South African Institute for Medical Research to several pools at Mayville and Sydenham, and we collected about 350 snails from one pool where *Physopsis africana* was heavily infested with schistosomes and *Limnæa natalensis* with the larvæ of fasciola. In the *Medical Journal for South Africa*, January, 1920, Dr. Annie Porter stated that she had found both *Schistosoma hæmatobium* and *Schistosoma mansoni* in these two common species of fresh-water snail, and in *Parasitology*, September, 1920, Dr. E. C. Faust reported both parasites in the material I sent him from *Physopsis africana*.

On June 11th, 1921, a boy was brought to me for treatment who had suffered from constant hæmaturia of 18 months' duration, but no other symptoms, since bathing in these pools at Sydenham. Microscopic examination of the centrifugalised deposit of urine passed revealed the presence of both lateral and terminal-spined ova, the latter being much more numerous. Both forms were about the same size, being from 0·12 to 0·15 by 0·06 mm. in diameter: the lateral spine was about twice the size of the terminal one.

In view of the more serious nature of infection with *S. mansoni* every endeavour should be made to eradicate the snails from these heavily-infested pools. Since the introduction of white duck[1] on the pool where Dr. Porter and myself collected so many in August, 1919, this water has remained free from them.

Durban.

A CASE OF
HUMAN ANTHRAX IN BUGANDA KINGDOM.

BY W. L. PEACOCK, M.B., B.CH. GLASG.,

DISTRICT MEDICAL OFFICER, UGANDA;

AND

H. LYNDHURST DUKE, O.B.E., M.D. CANTAB.,

BACTERIOLOGIST, UGANDA DISTRICT.

THE following case is reported as being the first instance in Buganda proper of an infection of man by *B. anthracis*. Human infections have been reported by Spearman in 1917 from Jinja, in the Eastern Province, and by Taylor from Ankole, the great cattle country in the Western Province of Uganda Protectorate. Spearman's case was not subjected to a full bacteriological examination, but Taylor isolated an organism in pure culture which corresponded, in so far as it was tested, to *B. anthracis*. The disease in animals has been known for some time to the Veterinary Department, in East Africa at any rate, and Taylor, as the result of a careful inquiry in Ankole, found that anthrax was well known to the Banyankole herdsmen. The history of the present case is briefly as follows:—

On Feb. 15th, 1921, a Muganda bricklayer, engaged on the construction of the venereal hospital at Mulago, was sent to hospital with a rough diagnosis of abscess of the jaw. Suspicion was aroused by the trifling character of the pain in comparison with the intensity of the swelling and œdema. On the edge of the right jaw there was a slightly raised tuberculated oval ring, some 1½ by ¾ inches in extent; there were no vesicles. The centre was slightly depressed and considerably darker than the skin in general. A dense infiltrated area surrounded the ring and extended for about an inch all round, fading into the œdema. The latter was so intense as to be almost fluctuating; it extended from the zygoma to the clavicle, and caused a certain amount of obstruction to respiration. There was surprisingly little pain. The temperature on admission was 100° F. The patient, whose work had nothing to do with hides or cattle, stated that he had bought and cut up some of the flesh of a bullock which was alleged to have been gored by another—probably a Luganda term for "death from unknown causes." Three days later he noticed a small papule on his cheek which he scratched, and it had gone on increasing in size from that time up to his admission to hospital some six days later.

On admission the pustule was at once excised and the wound painted with pure carbolic, partly closed by stitches, and a wet carbolic dressing applied. The temperature at once fell, and remained practically normal until his discharge three weeks later; the œdema subsided and had almost disappeared at the end of a week. A smear examined immediately after the excision showed typical anthrax bacilli in pure culture. They occurred singly or in short chains of two or three.

Bacteriological Report.

Tissue received 16/2/20 in saline; section prepared, revealing large bacilli scattered through tissues bordering on wound: bacilli Gram-positive. The blood-stained saline showed numerous similar bacilli in very long chains, the ends being cut off square. A portion of the material was repeatedly washed in sterile saline and rubbed on agar slopes, which were incubated at 37° C., aerobically and anaerobically. Vigorous growth resulted, under both conditions, of mixed culture of Gram-positive cocci and the large bacillus. The bacillus was easily isolated in pure culture. The organism answered to the classical description of the anthrax bacillus. The square-cut ends were most obvious in preparations lightly fixed with heat. In 36–48 hour cultures spore-formation was observed; spores central. Bacillus immobile; tended to form very long chains in liquid culture media; liquefied gelatin in funnel-shaped manner, the 25 per cent. gelatin used in this climate hiding the finer characters of the growth. Grew well on agar, aerobically thought, that the drain upon the glycogen of the maternal liver is brought about by pregnancy. One of the functions of the placenta in its early stages is to store glycogen for the growing fœtus.[22] In this way it functions for the fœtal liver until that organ is able to store its own reserve carbohydrate, and during this period of storage it is the glycogen of the maternal liver upon which it draws for its supply. With the placental formation complete, a condition of equilibrium establishes itself between the placenta and maternal liver, and the excessive drain being lessened the glycogen then comes to its normal amount, all fatty infiltration or degeneration disappears, and with it there is a cessation of vomiting or nausea. The carbohydrate theory is thus capable of explaining the major periodicity as well as the minor periodicity of nausea and vomiting in pregnancy.

---

[1] See reference in THE LANCET, 1919, ii., p. 636.

Insufficiency of Hepatic Glycogen persisting throughout Pregnancy.

There are also a few cases in which the nausea and vomiting continue after the fourth month, and may be present throughout the entire period of gestation. It is assumed in such cases that an equilibrium between the placental and hepatic glycogen is never reached, and the depletion of the maternal stores continues. This is possible because Slemons[23] has emphasised the demand of the fœtus for carbohydrate throughout its intra-uterine life. The fat of the fœtus comes probably from carbohydrate, and not from maternal fat. Hence if the equilibrium just referred to is not established, and the placental stores of glycogen are not sufficient to act as a buffer between fœtal demands and maternal supplies, the condition of insufficiency of hepatic glycogen will persist throughout the entire pregnancy.

It is evident that if the dual periodicity of the nausea and vomiting in pregnancy is accepted as the criterion whereby theories of its ætiology are judged, that the carbohydrate deficiency theory is the only one which satisfies both conditions. Auto-intoxication, disturbances of internal secretions, neurosis, may explain part of the phenomena, but can only be secondary in origin, though they may become so large that clinically in some cases they assume a primary importance. Moreover, some of these act either directly or indirectly upon carbohydrate metabolism, and may thus reinforce the original fault. It is also apparent that under the title of nausea and vomiting in pregnancy we have not included those cases which Williams [24] classifies as reflex, conditions in which malpositions of the uterus, ovarian tumours, &c., are to be set down as the inciting cause of the disturbance. Such cases, it is believed, are rare, and surgical treatment is the only procedure.

B. *Secondary Ætiological Factors.*

Intestinal Intoxication.—No one can doubt the importance of regular bowel movement in ordinary health, and it is equally important in the pregnant condition. Dirmoser [25] was responsible for the emphasis which has rightly been placed upon this factor, and several cases have come under observation where a certain degree of nausea in a pregnant state has indubitably been due to this cause. To ascribe to intestinal intoxication a primary ætiological importance is, however, to place it in a wrong position. Such cases as we have seen would have shown a degree of nausea even if pregnancy had not been present. They were cases in which the patient had suffered from a glycogenic disturbance of the liver with its accompanying nausea and vomiting, and had reacted favourably to carbohydrate treatment. Enemata had ceased, and the patient was on a liberal diet, when a slight degree of nausea returned. Fearing a relapse to her original distressing condition, the symptom of the nausea is exaggerated, with a depressing mental effect. The most careful examination of the urine fails to reveal any acetone bodies, and a purgative is followed with good results and a disappearance of the nausea. Whether or no the liver of the pregnant animal possesses a lowered detoxicating power by reason of lowered glycogen content it is, in our opinion, not possible to state at present. Certainly the protective action of a previous high carbohydrate diet makes the liver less susceptible to delayed chloroform poisoning.[16] Moreover, it is interesting to point out that after the carbohydrate treatment advocated in this and the previous paper, with its high amount of vegetables and with lactose by mouth, has been continued for a little time, certainly all danger of intestinal intoxication inciting another attack of nausea is reduced to a minimum, as the change in the direction of a putrefactive to an acidophile bacterial flora is well known on such a diet.[26]

Neurosis.—This factor is undoubtedly an important one; so important clinically that it has been given a premier place by many observers in this field. Nevertheless, for the reasons which we have previously stated it has been here placed as a secondary ætiological factor. A normal pregnancy is marked by heightened nervous reflexes,[27] and an unduly sensitive sympathetic nervous system can only have one effect upon the store of hepatic glycogen. It will result in its diminution. The effect of excitation of the sympathetic nervous system upon glycogen is well known to produce an excess of sugar in the blood at the expense of the glycogen in the liver, and it is thus seen how this neurotic factor will aid and reinforce the original primary factor. Thus the importance of rest and isolation cannot be too strongly emphasised. The many and varied reports of cures by suggestion, or by some trivial procedure, thus fall into their place. The excitation of the sympathetic nervous system is brought under control, and with it a diminution of the drain upon the glycogen, and a consequent return to more normal conditions. Quantitatively, the factors of pregnancy and neurosis may vary to such an extent that the second may become the greater of the two, and thus present itself as the major factor from the therapeutic standpoint; nevertheless, the metabolic factor must not be overlooked, otherwise the condition may simply recur, as is instanced in Williams's classic paper [24] (Cases 5 and 7).

Pernicious Vomiting.

In the foregoing paragraphs, then, it has been proposed that the primary ætiological factor in the nausea and vomiting of pregnancy is a lack of glycogen in the liver of the mother, with intestinal intoxication, and neurosis, as secondary factors, the metabolic and neurotic factors reinforcing one another; fatty infiltration of the liver ensues, and consequent upon the subsequent nausea there arises a positive distaste and intolerance for food, resulting in starvation. The outcome is the so-called pernicious vomiting. The influence of the resulting starvation has been very clearly emphasised by Underhill and Rand,[12] who ascribe to it the whole changes in the urinary pictures of pernicious vomiting. Their views have met with criticism, but it has only been that of degree. Ewing,[28] while admitting that starvation has an influence on the picture, claims that it is not an entirely adequate explanation. Gilliatt and Kennaway[29] point out that ammonia coefficients in pernicious vomiting rise more rapidly, and to greater heights, than in simple starvation. Neither criticism, in our mind, destroys the value of the arguments of Underhill and Rand; they merely emphasise that to starvation there should be added a further factor or factors. The lack of carbohydrate in inanition which is responsible for the urinary changes which have been found, is intensified in pregnancy by the factors which we have just previously been discussing, and we believe that it is the speed with which the changes occur that constitute the peculiarly vicious and dangerous condition which one meets with in pernicious vomiting. Without this added strain of pregnant growth, starvation changes would tend to come to equilibrium, until the approach of death itself.

We have thus put forward in a general way a hypothesis to explain the nausea and vomiting of pregnancy. In our opinion, it makes the fewest assumptions and is consistent with the greatest number of facts. It does not assume any specialised toxæmia of pregnancy was the peculiar duty of the group to ensure that the outcome of the discussion should not be lost sight of. The question of county survey was a subject which was receiving consideration by the group, and it was now proposed to approach the War Office with a view to further the work.

SOCIÉTÉ DE THÉRAPEUTIQUE DE PARIS.

AT a recent meeting of this Society Mr. **PIEDALLU** made a communication on a case of Uncontrollable Hiccough Cured by Aspirin. The patient was an alcoholic man, aged 67, suffering from pneumonia and delirium tremens. The hiccough had lasted for five days and five nights in spite of all the usual antispasmodics administered, such as belladonna, camphor, bromides, &c. A gramme of aspirin was then given as recommended by Petgès at a previous meeting of the Society, and within 24 hours the hiccough was cured.—Mr. R. **HUERRE** read a paper on the Solubility of Sulphur and its Clinical Applications, in which he maintained that sulpho-carbonate solutions of sulphur should be prepared with precipitated sulphur, and not sublimed sulphur, containing a large proportion of insoluble sulphur.—Mr. **HENRY BOURGES** read a paper on the Treatment of Acute and Chronic Gonorrhœa by Permanganate of Silver. The silver salt was used in very dilute solution, which was prepared with hot water immediately before use, the injections being given as soon as the solution became cool. In acute urethritis daily lavage with 0·05 g. per 1000 was employed, and in chronic urethritis a solution of 0·10 g. was given daily or every other day. In washing out the bladder progressively increasing doses were given, commencing with 0·02 g. at first, and raised the following days to 0·03, 0·04, and 0·05 g. The silver salt gave better results when employed from the first than permanganate of potash.—In a paper on Opotherapy and Mild Forms of Graves's Disease MM. **MARIE** and **FOURCADE** reported ten cases in women, aged from 19 to 47, under treatment for mild attacks of Graves's disease which were apparently due to emotion and commotion connected with the war, such as air-raids and long-distance bombardments, but really caused by old-standing disturbance of the glands of internal secretion. The diagnosis was confirmed by the improvement following treatment by ovarian or pituitary extract.—Dr. **NAAMÉ**, of Tunis, read a paper on the Treatment of the Vomiting of Pregnancy by Thyro-ovarian Extract. He referred to his previous paper read before the Society in 1905, when he attributed the vomiting of pregnancy to auto-toxæmia due to thyro-ovarian insufficiency. The disappearance of vomiting about the middle of pregnancy was due to establishment of a glandular equilibrium owing to hypertrophy of the thyroid gland. Thyro-ovarian opotherapy, by favouring the development of this hypertrophy, caused a rapid cessation of the vomiting. A cachet containing thyroidin, 0·05 g., and ovarin, 0·10 g., was given three or four times a day, half an hour to an hour before food. Mr. Naamé stated that he had employed his treatment with success for 19 years.—Mr. **AUGUSTE LUMIÈRE**, of Lyons, read a paper on Boro-potassic and Boro-sodic Tartrates, in which he stated that he had prepared a boro-sodic tartrate which appeared to possess all the conditions required to obtain the maximum advantages from boric acid with the minimum drawbacks. He claimed that the substitution of boro-sodic tartrate for potasso-sodic tartrate was justified on chemical, physiological, and clinical grounds.—Mr. G. **LEVEN** read a paper entitled "General Alimentary Therapeutics," in which he maintained that there need be no special diet for different diseases. What was harmful to the dyspeptic was injurious to the cardiac, the renal, the tuberculous, &c. The variations in a particular diet, like the prognosis, should be determined by the gravity of the disease and not by its nature.

REVIEW OF PENSION APPEALS.—The Minister of Pensions was recently asked if he was aware of many cases of claims being disallowed by the pensions appeal tribunal, in which the decision had not been in accordance with the medical evidence or had been based on inaccurate and insufficient evidence or a faulty record of the medical history or record of service of the claimant; and whether any machinery existed or could be created through which cases of hardship arising on any of the grounds indicated could be reopened and reviewed.—Major Tryon replied that the pensions appeal tribunals were independent statutory bodies under the control of the Lord Chancellor, and that their decisions were final and binding on both the man and the Ministry. It was the practice to furnish the man with a précis of the evidence, if he so desired, thus giving him an opportunity of calling attention to any omission which he considered might be prejudicial to his claim.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT NEWCASTLE-ON-TYNE.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

WEDNESDAY, JULY 20TH.

At the first session, Prof. **MATTHEW J. STEWART** (Leeds), the President, being in the chair, a discussion took place on

Hæmochromatosis.

Prof. J. **SHAW DUNN** (Glasgow) said that the term hæmochromatosis had come to be applied to a peculiar morbid condition, characterised by an accumulation of free iron-containing pigment in certain parenchymatous organs and in the skin, associated with interstitial fibrosis of the liver and pancreas, and, in some cases, with glycosuria. The liver, pancreas, and retroperitoneal glands showed a peculiar rusty colour, and gave an intense Prussian-blue reaction. Most other organs, although they might not be obviously pigmented, also gave the iron reaction on testing. Histological examination revealed the presence of brown granular pigment in proportion to the strength of the iron reaction seen on testing macroscopically. If cold hydrochloric acid were employed, the granules in the liver cells gave an intense blue colour, but the pigment in the fibrous tissue coloured a greenish brown. It would therefore appear that the iron was chemically in a more free condition when first deposited in the liver cells. In the pancreas, the islets of Langerhans were less pigmented than the ordinary gland tissue. Apart from the liver and pancreas, the iron granules were not associated with special degenerative phenomena of the tissues. The disease was usually seen in middle-aged patients, and the early stages were unassociated with symptoms. Neither pigmentation nor cirrhosis were primary symptoms; both were probably due to a common cause. Chemical examination of the organs showed that while there was no evidence of alteration in the total amount of iron in the blood, the excess in various organs was very great. The liver contained about 100 times the normal percentage. Even if all the iron ingested in the food were retained in the body, it would take at least three years for the accumulation of the amount seen in hæmochromatosis. In point of fact, retention of iron was not always absolute. None had been discovered in the urine by different observers, but a certain amount, though less than normal, was excreted in the fæces. This meant that the period of development of hæmochromatosis must be more than three years, and the iron accumulation was in all probability going on during the whole life of the patient. The excess of the iron was not due to an excessive breakdown of red cells; probably the condition was the outcome of a congenital metabolic peculiarity.

Dr. W. H. **MAXWELL TELLING** (Leeds) said it was still an unsettled question as to whether hæmochromatosis was a separate disease or just a stage of development of certain forms of cirrhosis of the liver, but the main clinical and pathological features were so distinctive that most observers regarded it as a definite entity. It occurred between the ages of 30 and 60, and was almost exclusively confined to males. The disease lasted two to three years as a rule, and there was sometimes an alcoholic history. Diabetic phenomena were slight or moderate, and occurred, if at all, late in the disease. The liver was considerably enlarged, and abdominal distension with attacks of diarrhœa, alternating with constipation, were common. The pigmentation of the skin varied from a leaden colour to a more definite bronzy appearance. The patients were curiously listless and apathetic in a way that was often seen in Addison's disease, to which the pigmentation added another resemblance. The disease was uninfluenced by treatment, and there was progressive cachexia till improved, and the acetone bodies continue to be found in small amounts in the urine, the introduction of protein into the diet need not be delayed until their actual disappearance. Usually, however, there is a close correspondence between the acetonuria and the clinical condition. Cream, butter, eggs, fat bacon, and fried dishes are best deferred until the patient has been for some time on the carbohydrate-protein diet, and even then should be introduced cautiously, and used sparingly.

B. *Intestinal Intoxication Factor.*—The bowels, if at all constipated—as they usually are—are opened by an enema or laxative. As far as laxatives and purgatives are concerned we have only one observation to offer. Avoid phenolphthalein and calomel. Almost all cases of severe vomiting show a slight degree of albuminuria, and although it is of so slight a degree that it is usually neglected and disappears without any treatment, nevertheless we do not think it worth while to risk aggravating it by the use of phenolphthalein or calomel. Once the high carbohydrate diet is established, the amount of vegetables and fruits is usually sufficient to keep the bowels in open condition. The milk-sugar is also useful in suppressing the putrefactive bacteria.

In addition considerable quantities of fluid are always urged by mouth. Any toxic substances absorbed from the bowel, or any produced by the maternal liver in its process of fatty degeneration, are thus kept at a minimum concentration in the blood and tissues. This applies especially to severe cases.

C. *The Neurotic Factor.*—Rest in bed with complete isolation is advocated at once for all cases in which the neurotic factor is recognised. Such a case is best treated at a hospital, as the requisite degree of isolation cannot be attained at home, even with a trained nurse in charge. Heavy doses of sedatives are usually rigorously avoided. On admittance to the hospital half to one grain of codein may be used for the first night to counteract the exciting effect of the removal and the new surroundings. After that, however, the only sedative allowed as a matter of routine is a mild dose of bromide (20 to 30 gr.) given by bowel in the evening. Very strict attention is paid to the other two factors. Visitors are rigorously excluded. In a few rare cases, where the patient is of a very excitable temperament, the bromide may be continued in each enema for a few days.

Summary.

It has been proposed that the primary ætiological factor in the nausea and vomiting of pregnancy is lack of glycogen in the maternal liver.

That secondary factors are intestinal intoxication and neurosis.

That as the condition progresses starvation and possibly dehydration intensify the symptoms to a degree known as pernicious vomiting.

That the correct therapy consists in the recognition of the value of the factors and bringing them under proper control by the following means:—

(*a*) The use of glucose to restore and maintain the glycogen content of the maternal liver; (*b*) the keeping open of the bowel; (*c*) rest and isolation, with a cautious use of sedatives to control the neurosis; (*d*) the use of water to combat any dehydration.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF
ABSCESS OF THE BREAST
OCCURRING IN A TYPHOID CARRIER.

By S. C. DYKE, M.B., D.P.H. OXON.,
PATHOLOGIST TO THE CLINICAL UNITS, ST. THOMAS'S HOSPITAL.

ALTHOUGH abscesses due to *B. typhosus* have been reported as occurring in a number of different sites, I have not in the literature come across an example of location in the breast. It has accordingly been considered worth while to report the following case.

The patient, a married woman aged 30, reported in the out-patient department of St. Thomas's Hospital on March 15th last, complaining of a lump in the right breast, which she had first noticed about three months before. It had shown no signs of activity until about three weeks earlier, when it started to enlarge and became somewhat painful. The lump was diagnosed as a carcinoma, and the patient was directed to come to the hospital a week later for admission, with a view to its removal.

Patient was admitted to the surgical unit wards under Sir Cuthbert Wallace on 22/3/21. By this time there was a well-defined tumour, occupying almost the whole of the right breast, but inclining a little to the inner and upper part. It was adherent to the skin, which was inflamed, just above the nipple, and fluctuation could be elicited in this spot. There was no discharge from the nipple; it was in no way adherent to the deeper structures and no enlarged glands could be made out in the axilla. Patient's temperature was 100° F. Diagnosis was altered to one of mammary abscess. On the following day the tumour was incised and drained by Mr. W. W. Wagstaffe.

On examination in the clinical units' pathological laboratory the pus was found to be of a viscous nature; the cells were so degenerate that the order to which they belonged could not be determined; no organisms were seen in stained films. On culture the pus gave a pure growth of a Gram-negative bacillus. In the ordinary routine cultures of this organism were made in MacConkey broth and in gelatin by stab. No liquefaction of the gelatin occurred and there was no change in the MacConkey. The organism was now put up in mannite and broth; it was found to be motile and to produce acid only in mannite. It was accordingly put up against the Lister Institute typhosus agglutinating serum (titre of 2000) and agglutination was obtained to the full titre.

By the time that this result had been obtained the patient had left hospital with the operation wound almost entirely healed. On April 4th she was seen in the out-patients department and questioned as to past history of typhoid infection. The patient stated that up to October, 1920, she had been for four years resident in India, but had no knowledge that she had ever had typhoid. In July, 1920, while resident at Quetta, her two children had been ill with what was diagnosed as measles; she had nursed them and became affected with what was thought by her doctor to be the same disease. From that time until she left India in October, 1920, her health was good, but while coming over in producing cancer in mice by inoculation with these organisms. Fourthly, he had produced a focal reaction in the tumour after injection of minute doses of vaccine from these organisms. He concluded that cancer was due to anaerobic bacteria attacking cells during a period of enfeebled resistance.

Dr. J. A. MURRAY (Director, Imperial Cancer Research Fund) said that mammary tumours in mice were common, and this, together with the very great variability in the length of incubation in Dr. Robertson's experiments, and the fact that there was no constant relation between the site of inoculation and the site of the tumour, caused him to doubt whether there was any specific relation between the organisms and the tumours described. Dr. Murray saw the rod-like structures demonstrated at Oxford 14 years ago, but he still held that they were not bacteria. He mistrusted results which depended on metallic impregnation methods of staining.

Blood Platelets in Scurvy.

Dr. S. PHILLIPS BEDSON (Newcastle-on-Tyne) read a paper on the Blood Picture in Scurvy with Particular Reference to Platelets. In pathological conditions, he said, which are accompanied by a diminution in the number of blood platelets, a tendency to hæmorrhage is almost always observed. In scurvy we had a clinical condition in which hæmorrhage was a constant feature. The question therefore arose as to whether or not the platelets were reduced in numbers in the acute stages of scurvy. Dr. Bedson showed tables of results obtained from experimental animals and from one human case. In all neither platelets nor red cells were diminished. Indeed they increased somewhat in what was termed the "pre-scurvy" period, dropping again to normal at death.

Pathology of Gastric and Duodenal Ulcer.

Dr. A. G. GIBSON (Oxford) described his experiments with a streptothrix obtained from a case of acholuric jaundice. The organism was injected into the peritoneum of monkeys. After some months the monkeys were seen to fail in health; they had occasional rigors and tenderness over the spleen. Post mortem several circular ulcers were found in the stomach; the spleen was fibrotic; the liver showed areas of atrophy, and there were hæmorrhages in the lungs. Microscopically endophlebitis was seen in all these organs. Dr. Gibson said that the gastric ulcers were produced by infective material passing to the stomach via the splenic veins. He did not think, however, that this was the usual method whereby gastric ulcer was caused in the human subject.

Dr. D. P. D. WILKIE (Edinburgh) said he was about to describe a pathological and clinical entity not usually recognised by pathologists. This was a condition of dilatation of the first three portions of the duodenum with congestion and hypertrophy of its walls. Chronic vomiting was a symptom in many cases. In one case there were periodic attacks of acute pain of such a nature that the disease was mistaken for gall-stones. The duodenum was dilated up to the point where it is crossed by the mesenteric artery. In cases where there was slight visceroptosis, so that the small intestine hung over the brim of the pelvis but did not reach its floor, the duodenum might be subject to intermittent compression by the artery. Cases, however, occurred in children, and were then undoubtedly of congenital origin. The treatment of the condition was to anastomose the third part of the duodenum to the jejunum. Sometimes it was possible to raise the colon and to relieve the obstruction in this way. The condition might be associated with duodenal ulcer, acute pancreatitis, or with disease of the biliary apparatus.

Experimental Tar Cancer in Mice.

Dr. J. A. MURRAY gave a description of the work which he and Dr. W. H. Woglom (New York) had carried out in producing cancer by painting the skin of mice with tar. The tar was applied to the skin at the back of the neck two or three times a week for some months. Then, in a few animals, warty growths appeared and increased in size as long as they were painted. Portions of these growths were inoculated into the same animals, and they continued to grow progressively and sometimes formed metastases. When autogenous inoculation was performed with benign tissues growth ceased. Malignant tumours grew progressively. The great difficulty with which all workers in cancer research were faced was what criteria should be adopted in deciding whether a growth was innocent or malignant. Tar cancer had been produced by Japanese observers, but their observations did not prove that the growths so obtained were really cancerous.

Dr. GASKELL said that Dr. Murray's work was epoch-making, in that it pointed to a method which might be reliable in the study of cancer. He wished to know whether it was possible to perform the experiments in an aseptic manner, so as to eliminate the bacterial factor in the production of cancer.

Dr. FORD ROBERTSON congratulated Dr. Murray on his very interesting and important observation. The question of ætiology of cancer was not solved. He thought that the skin lesion produced by painting with tar opened the way for infection.

Dr. A. LEITCH (Cancer Hospital, London) said that spontaneous tumours often developed during experiments. Carcinoma could not be diagnosed with certainty by pathological methods. Even if a tumour grew progressively on transplantation it was not necessarily malignant.

Dr. MURRAY said that sterilisation was ideal but not possible in the animal body. He agreed with Dr. Leitch that there was no definite line of demarcation between malignant and benign tumours.

FRIDAY, JULY 22ND.

On this day a joint discussion with the Section of Medicine and of Physiology, Pharmacology, Therapeutics and Dietetics took up the subject of

Renal Function Tests.

Prof. HUGH MACLEAN (London, St. Thomas's) said that in recent years much attention had been paid to tests for renal function, and that now we were in a position to assess the condition of the kidney with some degree of accuracy. He would devote himself chiefly to the clinical side of the question, and to acute nephritis in particular, since in the latter disease the tests were of special importance. Retention of salt was important in acute nephritis. One of the first indications of improvement was the return of salt in the urine, and this generally occurred simultaneously with diuresis. The stimulation by retained urea and by œdema produced diuresis as soon as the kidney cells could respond. In well-marked acute nephritis no tests for renal efficiency were necessary; the condition was sufficiently indicated by the symptoms. But later, in order to ascertain what progress was being made, tests were of the greatest value. One of the most important was the determination of urea in the blood. The normal amount was about 20 to 40 mg. per 100 c.cm. of blood. Until three-quarters of the kidney substance had been put out of action no retention of urea took place. The fallacy of the blood-urea test was that, in chronic cases, it gave no indication of deranged function until the disease had reached such a stage that the clinical condition alone would give the information required. In acute nephritis, however, the test was invaluable. Blood urea rose steadily in fatal cases even when the clinical condition seemed good. Concentration of urea in the blood had no relation to uræmia, except that both were the result of renal insufficiency. Reduction of protein in the diet reduced the urea but did not stave off uræmia. As regards other methods, the diastatic test was of some value, but he would not rely on it alone. The phenol-sulphone-phthalein test was useful but difficult to carry out with accuracy. The urea-concentration test was simple to carry out and gave very constant results; it had the advantage of and anaerobically at 37° C. Growth creamy at first, becoming greyish and dryer later on; faint mousy smell. Milk curdled and digested. The edges of the growth on agar showed little tongue-like projections, which, in common with the isolated colonies on agar, showed the beautiful wavy appearance caused by strands of parallel chains of bacilli which is described and figured in the text-books. Isolated colonies on agar plates presented a very characteristic appearance suggestive of tiny three- or four-fingered star-fish, or catherine wheels. In texture they looked like little bedraggled tufts of wool. In peptone water the woolly appearance was very noticeable in the masses of growth which, on gentle shaking, detached themselves from the surface clumping.

The serum of the patient taken on March 8th agglutinated up to 1/80, with traces at 1/160. The bacillus refused to emulsify very evenly either in normal saline, 0·1 per cent. saline, or distilled water, but controls were set up with normal saline and with normal human serum, and the results were definitely positive. The tests were performed with 0·3 c.cm. unit volumes, and incubated for two hours at 37° C., two hours at 56° C., and confirmatory readings taken overnight.

Animal Inoculation.

A rabbit and three healthy wild rats were inoculated. The rabbit received two drops of a saline emulsion of the bacillus subcutaneously on 10/3/21. The animal died on the 18th; post mortem the spleen was small; mesenteric vessels much injected; peritoneal cavity contained blood-stained fluid. The heart-blood gave a pure culture of a Gram-positive bacillus corresponding in every way with the organism inoculated. The rats were all inoculated in the same manner on 12/3/20. Rat 292 was found dead on the morning of 13/3; the other two were alive on this date, but were found dead on 14/3/20.

Post-mortems.—Rat 292: spleen slightly enlarged, injected mesenteric vessels; small amount of exudate in peritoneal cavity; heart-blood gave the bacillus in pure culture; spleen smear showed the bacillus together with a Gram-negative bacillus. Rat 293: spleen much enlarged; liver enlarged, soft and friable; mesenterics injected; reddish fluid in peritoneal cavity, heart-blood gave the bacillus in pure culture. Rat 291: spleen and liver not enlarged; gelatinous red-tinged exudate in peritoneal cavity; great injection of mesenteric vessels; heart-blood gave the bacillus in pure culture.

Sections of the spleen and kidney of rat 293 showed the bacillus more numerous in the spleen. Sections of rat 294 showed bacilli in the spleen, but not in the kidney.

Medical Societies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

NAVAL, MILITARY, AND AIR FORCE HYGIENE GROUP.

A meeting of this group of the Society of M.O.H. was held at 1, Upper Montague-street, on June 30th, Lt.-Col. H. R. Kenwood, the President, being in the chair, when Col. H. W. Grattan, Deputy Director of Hygiene, War Office, read a paper on the

Coöperation between the Civil and Military Sanitary Authorities during a Great National Emergency.

Col. Grattan said it was clear that coöperation would be simplified when both the military and civil sanitary authorities had a good working knowledge of each other's administrative machinery and organisation. In order to ensure the application of local knowledge it would be necessary for the civil and military to be in practical communication with one another—not only at headquarters, but also in the outlying areas and districts. The following list of subjects would require consideration: (*a*) Inter-notification of infectious diseases; (*b*) water-supplies, including extension of water mains; (*c*) drainage and conservancy arrangements; (*d*) control and accommodation of cases of infectious disease; (*e*) disinfection of clothing and blankets; (*f*) arrangements for ablution; (*g*) destruction of refuse; (*h*) supervision over the preparation of the food-supplies for the army; (*i*) the prevention of spread of infectious disease on mobilisation; and (*j*) the treatment of soldiers discharged from the army on medical grounds.

The secret of success in organisation lay in decentralisation, and one of the first steps would be to arrange a conference between representatives of the Ministry of Health and the War Office with a view to coördinated action. Liaison officers would be required in London, and in the provinces the Ministry of Health should allot medical inspectors to certain administrative areas, with the special duty of assisting coöperation between military and local authorities. Instructions might be issued by the Army Council to commands, and circular letters from the Ministry of Health to civil sanitary authorities pointing out the means to be adopted to ensure coöperation. Col. Grattan referred to the circular letter issued by the L.G.B. early in the war to sanitary authorities in which the duties of an M.O.H. of a district containing troops were defined. Difficulties occurred later in bringing military and civil sanitary authorities into touch, as military officers were unaware of the boundaries of the civil sanitary districts; similarly M.O.H.'s lost time in tracking down the military officers. The two organisations differed widely, and in order to prevent confusion and overlapping it was essential for a military command to realise the principles on which the civil sanitary organisation of an area was based, otherwise delay would occur by reference to a central civil authority having possibly little immediate local jurisdiction. It would undoubtedly be an advantage if the county authority, which controls and administers measures relating to tuberculosis, small-pox, venereal disease, maternity and child welfare, and the pollution of rivers, would also take up the question of coöperation with the troops in matters of public health.

Lt.-Col. Caldwell Smith illustrated from his own experience the value of coöperation with local authorities by personally enlisting the sympathy not only of the M.O.H. of the area concerned, but also the sanitary inspectors and chairmen of public health committees.

Maj.-Gen. Sir W. G. Macpherson said that billeting was often unsatisfactory because the police made arrangements without in the first instance consulting the local sanitary authority. At the beginning of the war the L.G.B. gave every assistance to those entrusted with maintaining the health of the troops by sending medical inspectors to different parts of the country.

Col. Sir G. Sims Woodhead said that before the war no preparation had been made for a real sanitary service. This work fell largely upon the R.A.M.C. (T.F.), with its two sanitary companies, so that when war broke out this essential work was carried out by a few men. The time was ripe for organising the sanitary services and the liaison between the army and the civil services. To illustrate this need he instanced the erection of a hutted camp, with huts inadequately ventilated, where later an epidemic of cerebro-spinal fever occurred. One way of bringing about a closer coördination was for responsible civil posts to be made available to service-trained men on their retirement.

Surg.-Rear-Admiral Sir P. W. Bassett-Smith, speaking from the naval point of view, said that by the development of a naval health service a real effort was being made to bring about closer coördination.

Major J. Hutchinson Wood considered that medical officers had too often been overruled by the higher authorities in local commands, particularly in regard to the selection of camp sites.

Lt.-Col. Anderson said the quartering committees were excellent liaison arrangements, the local M.O.H. being a member of the committee. A scheme for coöperation had actually evolved towards the end of the war.

The President endorsed the opinion that full advantage had not been taken of local knowledge, little opportunity was given for local initiative. It the more usual type of abscess seen in infections by the commoner pyogenic organisms. There were also malignant endocarditis with infarcts in various organs and one case in which a piece of a clot riding astride a patent foramen ovale had broken off and lodged in the middle cerebral artery, causing softening of the brain. The teaching value of such a collection is evident. In no way inferior were the series of organs in which each specimen illustrated a typical lesion. Each of its kind was perfect. Among the hearts were beautiful examples of pericarditis, and one especially where the sac was shown distended by a very large effusion. Similarly, in the lung series, a student might find examples of the principal diseases affecting that organ. The specimens were so good that the lesion could be identified at a glance. Among the stomachs was a remarkable dissection showing the lymphatics of that organ permeated by cancer. New growths of the alimentary canal were well represented, and there were several excellent specimens of foreign bodies, as well as of cancer, in the œsophagus.

A very interesting collection of syphilis in various organs was lent by Sir CLIFFORD ALLBUTT. Microscopical sections were appended to each of the organs shown. The series showing syphilis of arteries was extremely complete. Another beautiful exhibit illustrating a special paper was Prof. STEWART'S collection of organs from cases of hæmochromatosis. Portions of liver and pancreas, spleen and glands were shown from several cases. In three, carcinoma had supervened in the liver on the top of the primary lesion. Considering the rarity of carcinoma of the liver, its occurrence in such high proportion was very striking.

Among the exhibits illustrating recent research, mention must be made of Dr. DA FANO'S remarkable sections from cases of encephalitis lethargica. The first four preparations illustrated the pigmented and non-pigmented granules first discovered by himself in this disease. Others showed the typical perivascular and interstitial infiltration. In one very interesting acute case, where death took place on the third day of the illness, the infiltration was seen to be composed of polymorphs and macrophages instead of the usual lymphocytes and plasma cells. One section showed an inflamed salivary gland—an interesting confirmation of Netter's observation that as in rabies, so in encephalitis lethargica, the salivary glands may be the seat of infection. Sections from encephalitis lethargica were also shown by Dr. SHAW. They illustrated clearly the focal œdema, perivascular hæmorrhage, and neuronophagia seen in this disease.

Another exhibit of the results of research, which also illustrated a paper read at the pathological section, was shown by Dr. FORD ROBERTSON. He has by using special methods succeeded in cultivating an anaerobic diphtheroid organism from scrapings from malignant tumours, and seeks by his experiments to prove that this organism is the cause of cancer. His preparations showed cancerous tumours which had developed in mice following inoculation by this organism; the tumours were present in several different organs, although the inoculations had been made subcutaneously.

Among the pathological curiosities of the museum must be mentioned a case of malakoplakia of the kidneys and bladder. Only 22 instances of this rare disease have been reported and this is the only one in which the kidneys are affected. Macroscopically small greyish semi-transparent nodules are seen in the mucosa of the bladder and in the kidneys. These nodules tend to coalesce. Microscopically large characteristic cells are seen with cell inclusions somewhat resembling the corpora amylacea of the prostate. The cause of the disease is quite unknown, but it appears probable that it is due to an infective agent. Another unique specimen was a calculus hydronephrosis of the kidney due to cystin calculi. The dilated pelvis contained small round stones and a larger one blocked the ureter. A case of hypernephroma with secondary deposits in the heart and other organs was also shown. An astonishing tonsillar calculus, measuring two inches in length, excited considerable curiosity. The specimen came from the East, the home of pathological monstrosities. Among the tumours a rare specimen was that of lipoma glandulare, lent by the West London Hospital. The fat in this tumour has the peculiar arrangement of that found in hibernating glands of animals. Such tumours arise in the region of the shoulder and are thought to be derived from a vestigial hibernating gland in man.

Treatment by radium was illustrated by means of photographs and the various tubes used were shown.

Besides pathological specimens a large and extremely interesting collection of X ray plates and prints was on view. They ranged from an excellent series illustrating bone deformities to tuberculous lungs, which were illustrated by some very beautiful photographs. A very interesting exhibition was that contributed by Mr. THOMSON WALKER of X rays of renal calculi. The prints showed the calculi not only from the antero-posterior aspect, but from the lateral view as well. By this method renal calculi can be differentiated with certainty from gall-stones. With the technique elaborated by Dr. KNOX, gall-stones, which were in former times only seen occasionally, can now be revealed with certainty. In one case renal and biliary calculi were present together and were clearly seen in the photograph.

Whether looked at from the teaching or from the purely pathological standpoint, the museum was a remarkable one. Museum workers might gain many ideas in the arrangement and mounting of specimens, while few could examine the collection without carrying away with them some new facts. The organisers may be congratulated on their achievement.

SECTION OF PHYSIOLOGY, PHARMACOLOGY, THERAPEUTICS, AND DIETETICS.

WEDNESDAY, JULY 20TH.

The proceedings began by a resolution moved by the President, Prof. H. H. DALE, F.R.S., and seconded by Prof. A. V. HILL, F.R.S. (Manchester), of regret and condolence on the sudden death of one of the vice-presidents, Prof. J. A. MENZIES.

Various Uses of the "Hot Wire."

The first paper was by Prof. HILL, the subject being "The Use of the Hot Wire for Investigating (*a*) the Time Relations of the Pulse; (*b*) the Characteristics of Voluntary Contractions in Man." The principle of the use of the hot wire is that if a platinum wire is heated by passing an electric current through it a puff of cool air on the wire will cause a change of electric resistance. This change can be recorded by means of a string galvanometer. The apparatus containing the hot wire was shown, and also the small funnel connected by an indiarubber tube, which transmitted the impulse from the pulse to the wire. Only the changes of current must be transmitted to the hot wire, and various methods were described to prevent the recording of the steady current used for heating the wire. A number of lantern-slides were shown illustrating the use of the hot wire. The tracings were in many cases taken simultaneously with a mechanical record by means of a mirror connected to a tambour. In all cases the records of the different phases of pressure in the pulse exactly coincided in the optical and hot-wire tracings. By this apparatus the velocity of the pulse can be very accurately measured, since simultaneous records can very readily be taken from different parts of the circulatory system. The apparatus is quite incapable of mechanical vibrations, and since the vibrations of the galvanometer can be completely damped an absolutely reliable record can be obtained. Since in tracings obtained by this method contamination by mechanical vibrations is prevented, this fact enables one by comparison to establish which of the vibrations obtained by other methods are mechanical in origin.

death. He considered that the condition was due to defective iron elimination, and that the cirrhotic process was secondary to the irritation by the massive pigment deposit. Primary carcinoma of the liver had occurred in several cases. He thought every case of cirrhosis of the liver should be carefully investigated from the hæmochromatosis point of view. In early cases the deposition of the iron pigment might be missed.

Discussion.

Dr. J. F. GASKELL (Cambridge) described a case which had been investigated by himself and Dr. Mackenzie Wallis. The conclusion arrived at was that the tissues had an abnormal affinity for iron. The condition of organs in normal and abnormal excretion of iron was interesting. In the kidney the iron was found in the glomeruli and tubules of the first order only. This was entirely different from its distribution in the conditions of blood destruction such as pernicious anæmia. In the liver the iron was accumulated round the bile canaliculi, and also in the walls of the bile-ducts. The condition suggested an attempted excretion by normal channels associated with rapid reabsorption. It was possible that there was an essential disorder of iron metabolism with the presentation of the iron to the tissues in an abnormal form.

Dr. MACKENZIE WALLIS (London, St. Bartholomew's) defined hæmochromatosis as a condition in which iron-containing pigments were deposited in certain tissues in abnormal amounts. In searching for cases of bronzed diabetes types he had come across various forms of pigmentation in diabetics, not due to iron. In xanthoma diabeticorum a canary-yellow pigmentation of the hands and feet was present. He was inclined to think that this pigmentation had no reference to hæmochromatosis, but was at present investigating a case. He regarded the cirrhosis as caused by the free iron pigment; the masked iron pigment represented an attempt on the part of the body to get rid of the pigment by means of the lymphatic system.

Dr. J. CRUICKSHANK (Aberdeen) described a case which had recently come under his observation but was not yet fully worked out. Golden-brown pigment which did not contain iron had been found in many organs. There was no obvious relation between P.M. and clinical symptoms.

Prof. J. M. BEATTIE (Liverpool) described a case in which diabetes had been present three years before bronzing of the skin, showing that diabetes was not always a late symptom. In this case a large quantity of iron had been found in the intestine.

Prof. STEWART said that probably hæmochromatosis was not such a rare disease as was thought. The diagnosis during life was difficult, but surgeons might throw more light on the subject by examining the abdominal glands in cases where a laparotomy had to be performed. It might be possible to detect iron pigment in the epithelial cells in the urine.

Prof. SHAW DUNN, in reply, said that the yellow, non-iron-containing pigment was probably the same as that found in brown atrophy of the heart, &c., and was not characteristic of hæmochromatosis. On the whole the appearances suggest that in hæmochromatosis the iron was first deposited in the cells on normal physiological lines, but in an exaggerated form. For the recognition of early cases it would appear that pigmentation of the skin was the likeliest feature to rely on.

The Streptococci.

Prof. BEATTIE said that the high frequency of hæmolytic streptococci in the human throat might explain the important rôle these organisms played as the secondary invaders in a multitude of diseases. At the same time it must be recognised that, like the pneumococcus or *B. diphtheriæ*, they might be present in the normal throat (14 to 90 per cent. of cases), and under certain conditions might become the causal agent of disease. It was significant that various acute infections started with a "sore throat." The importance of a systematic classification of streptococci was very great. The morphological and cultural reactions were unsatisfactory for the purpose, as the types defined by them had no relation to pathogenicity. Hæmolytic and immunological reactions were useful. Hæmolytic strains of streptococci were associated with acute infections. Technical difficulties in the way of agglutination and precipitation tests were great, but there was evidence that these were being gradually overcome, and that serums had been prepared which were highly protective to white mice against infections with organisms of the homologous type. From the experimental side it seemed perfectly clear that the streptococci of human origin were not a unit, but that several types existed; that these types could be differentiated by immunological and other reactions, and that homologous serum could protect against infections. At present these homologous serums were not of practical value in human infections, but the line of work opened up was of very great importance, and there was every hope that the results with antistreptococcal serum would be as brilliant as those obtained in the past with antimeningococcal serum.

Dr. H. WARREN CROWE (Harrogate) proposed to widen the discussion to include the non-hæmolytic streptococci such as the pneumococcus and *S. viridans*. He showed a medium composed of heated blood which would enable streptococci to be differentiated into a large number of types. He discussed the relation of the organisms to rheumatism. Seven or eight varieties of streptococci could be cultivated from one tooth, and in the treatment of rheumatoid arthritis a vaccine from each of these organisms must be prepared.

Dr. G. H. DIBLE (Southampton) said that the problems that confronted us were numerous and difficult. A classification to be effective must contain the following three points: (1) the tests used must be simple; (2) there must be clear lines of division between the groups; (3) the classification must have a definite meaning as regards pathogenicity. He divided the streptococci into two main groups—the hæmolytic and the non-hæmolytic. Each group had four sub-groups based on an association of characters, such as heat resistance, fermentation of sugars, &c.

Dr. J. W. MCLEOD (Leeds) described his experiments with hæmolytic streptococci. He was sceptical as to the value of specific serums. His serum did not protect rabbits inoculated with a virulent strain of hæmolytic streptococci, although normal horse serum had delayed the fatal result.

Dr. W. FORD ROBERTSON (Pathologist, Scottish Asylums) put forward a classification which had yielded satisfactory results. He found his methods of great use in the preparation of vaccines.

Prof. BEATTIE, in reply, said he was very sceptical of classifications based on one or two characters only. A classification should give some idea of the degree of pathogenicity and whether homologous serums could be used.

THURSDAY, JULY 21ST.

Relation of Carcinoma to Infection.

Dr. FORD ROBERTSON said that for many years he had maintained that carcinoma was an infection. He had found rod-shaped bodies in cancer cells, and he considered these as a stage in the life-history of a carcinomatous organism. Using special culture methods he had been able to convert aerobes into anaerobes. An anaerobe might get into a living cell and multiply, and then one of two things would happen: the cell might die, or growth might be stimulated. In the latter case the cell would divide and might acquire a habit of division. To confirm his hypothesis that cancer was caused by anaerobic organisms, he had recourse to four methods. Firstly, direct examination of epithelial cells showed that minute rods resembling bacilli were present in special areas. Secondly, he had succeeded in making cultures from the freshly scraped surface of a tumour, and had grown minute granular rod-shaped bacilli, similar to those seen in sections. Thirdly, he had succeeded issue, occurring in subjects after the appearance of lupus. Figures quoted from Forchammer, Besnier, Demme, Eibe, Leloir, Bendu, and others gave 21 to 62 per cent. of visceral tuberculosis, with death from phthisis in 5 to 21 per cent. of lupus patients. In this country he had not found any figures recorded showing such a great frequency of visceral disease. The family tuberculous history was of importance in the consideration of this question. In his own hospital cases of lupus there was a tuberculous family history in 23 compared with Sequeira's 40 and Bendu's 33 per cent. Dr. H. Osborne (deputy M.O.H., Salford) had furnished him with figures showing the incidence of cutaneous tuberculosis compared with other forms of tuberculosis for the last five years, which showed 2 per cent. of all cases. In the city of Manchester in 1913 the proportion of skin tuberculosis to other forms was about 3·5 per cent. From the Manchester and Salford Hospital for Skin Diseases a series of lupus cases (72), taken in the order of their notification about the year 1913, showed by 1921 visceral tuberculous disease in 11 per cent., with a fatal issue in about 4 to 5 per cent. (Dr. D. P. Sutherland). Of 50 cases of lupus vulgaris examined for signs of visceral disease, one had active phthisis which was prior to the lupus, two had the appearance of chronic phthisis with cough the only definite symptom and no other signs of activity without tubercle bacilli in the sputum, two presented evidence of old and apparently arrested phthisis. In the remaining 45 cases there were no physical signs distinctive of recent or old phthisis, though 21 of these allowed suspicion of tuberculous predisposition. There was a family tuberculous history in 12 cases (Dr. R. W. Marsden's report).

The discrepancy between the speaker's own and some of the continental figures could be interpreted in these latter through the contraction of visceral disease by predisposed subjects under their conditions of environment by the ordinary channels of infection without the lupus being itself causal. Otherwise we might reasonably expect greater uniformity in the figures of relative incidence from all countries. Dr. Stanley Griffith had found 50 per cent. cases from Dr. Lancashire's hospital yielding tubercle bacilli of bovine type. The great majority of the cultures were attenuated. His own conclusions were that whereas the causal relationship of primary visceral with secondary cutaneous tuberculosis was already established, the opposite causal relationship was not definitely proved, and that the majority of cases of cutaneous tuberculosis remained "good lives."

Discussion.

Dr. HALDIN DAVIS (London) did not agree with Dr. Lancashire's conclusions.

Dr. W. KENNETH WILLS (Bristol) mentioned that from some Bristol figures only 3 per cent. of his lupus cases showed other tuberculous lesions. As had been suggested to him the infection of the skin might occur from infected handkerchiefs through an abrasion. Lowering of resistance by tuberculin treatment might cause spread from the site of the local infection. He had seen Addison's disease follow the tuberculin treatment of a case of lupus. The high continental figures could be interpreted through the poor conditions, housing, &c., prevailing in some of the large continental towns.

Dr. R. CRANSTON LOW (Edinburgh) thought that this question should be looked at from the opposite point of view. The type of patient who had lupus was the type of patient with visceral tuberculosis. A probable high degree of sensitisation by avirulent tubercle bacilli suggested a good prognosis. Among patients without lupus there might well be an equal number with visceral tuberculosis, but such patients were not examined for the presence of tuberculous lesions without any local indication of the disease.

Dr. HENRY MACCORMAC (London) said that one of the most striking features of lupus was the distribution of lesions about the various orifices of the body. The connexion of visceral with skin tuberculosis depended upon the mode of infection. If the condition was usually a blood infection then most cases of lupus must be secondary to some internal tuberculous focus.

Dr. A. D. HEATH (Birmingham) considered that the bad hygienic conditions of cottagers might account for the high incidence among the rural population. He believed the cases due to infection with bovine types to be milder than the cases of human type infection. The more fibroid the lupus was, the greater was the involvement of the mucous membranes and the more likely to be followed by dissemination.

Dr. D. WELLS PATTERSON (Newcastle) had seen only four cases of lupus which were proved to have been followed by phthisis. He considered that the large number of cases of facial lupus was associated especially with lupus of the nasal mucosa.

Dr. S. E. DORE (London) had not seen one case of active pulmonary tuberculosis in association with active lupus. He believed that there might be auto-vaccination from the local lesion. In his opinion the clinical manifestations and behaviour of any case depended upon the anatomical disposition of the disease.

Dr. LANCASHIRE briefly replied.

Cutaneous Sensitisation and Focal Sepsis.

Dr. H. W. BARBER (London) read a paper on Cutaneous Sensitisation and Focal Sepsis in the Ætiology of Certain Skin Affections. He said that the first part of his paper would deal generally with protein sensitisation and focal sepsis, while in the second part some particular dermatoses would be considered. Our knowledge of protein sensitisation was based on the experimental work carried out on hay fever. For a long time the association of asthma with urticaria or eczema had been noted. Protein sensitisation was to a great extent bound up with the subject of food idiosyncrasy, and the periods of desensitisation resembled those of anti-anaphylaxis to experimental anaphylactic shock by protein injections. Many important papers had been written on this subject, especially in America, notably those of Schloss, Engman and Wander. He would draw special attention to the influence of (*a*) heredity; (*b*) gastro-intestinal disturbance in the occurrence of protein sensitisation. It was difficult to say how far the morbid reactions resulting from these idiosyncrasies to food, animal, or bacterial proteins were dependent on anaphylaxis. Concerning cutaneous tests for protein sensitisation he would say that a strong reaction was almost always an important aid to diagnosis and treatment, while a doubtful reaction might be equally important or of no practical significance. Grouped reaction occurred presumably dependent on a kindred chemical composition. In his own opinion the phenomenon of local sensitisation of the skin was of considerable importance. With regard to focal sepsis the commonest primary foci of infection were the teeth, tonsils, naso-pharynx and nasal sinuses, and possibly the intestines. In persons in whom digestion and assimilation were incomplete, or who suffered from inflammatory conditions of the intestinal mucous membrane, protein substances capable of acting as toxic antigens might be absorbed direct into the blood stream and provoke anaphylactic reactions. But other possible foci than those mentioned existed, such as the appendix, gall-bladder, lungs, ears, genito-urinary tract, and the female pelvic organs.

Turning now to individual skin affections or groups of affections he would say that typical cases of erythema multiforme as classically described by Hebra were probably always of bacterial origin, the organism being in most cases a hæmolytic streptococcus, as in purpura hæmorrhagica. One of the most widespread eruptions of erythema multiforme that he had seen occurred in a boy with chronic rheumatic heart disease within a few hours of tonsillectomy. The fact that the eruption recurred periodically in certain persons suggested that, like asthma and some forms of urticaria and eczema, it was an anaphylactic phenomenon. The majority of cases of erythema nodosum were, showing a lesser defect in the kidney than was shown by a rise in the blood urea. In order to carry out the test 15 g. of urea were given in 2 or 3 oz. of water. The patient emptied his bladder at the time of taking the urea, and again one hour and two hours later. If more than 2 per cent. urea was excreted, the kidneys were fairly healthy. As regards salt excretion, there was no means of testing it directly, but the defect would be shown by the presence of œdema. Salt was present in the body fluids in the proportion of 0·6 per cent. If the kidney was not excreting salt, water would be retained; if the secretion of water was deficient, salt would be retained so as to keep the percentage constant. Neither high blood pressure nor albuminuria was necessarily associated with renal defect. Examination of the kidney by means of these tests was extremely important, especially in surgical affections of the urinary tract, where the inefficient kidney was a contra-indication to operation.

Prof. W. Boyd (Manitoba) said that from the clinician's point of view the functional capacity of an organ was an essential point. It had been advised as an efficiency test of renal function that two-hourly samples of urine be collected; measuring the quantity and taking the specific gravity of each sample might give information of value. The normal kidney would eliminate amounts of urine varying according to the amount of fluid taken—the specific gravity varied widely. The sclerotic kidney would excrete practically the same amount of water and solid every two hours. This tendency to uniformity in the amount of urine and specific gravity was known as fixation of the kidney. Unfortunately "fixation" was not a reliable indication of impaired kidney function. Neither the potassium iodide nor the phenolphthalein tests were satisfactory. He preferred to place reliance upon the estimation of blood urea. In his experience, less than 50 mg. of urea per 100 c.cm. of blood had a favourable prognostic significance. If the blood urea rose over 50 mg. stringent non-protein diet was called for. Above 100 mg. the prognosis was exceedingly grave.

Dr. Mackenzie Wallis, after a considerable experience of tests, had limited them to four or five. The water test was simple and very efficient. 500 c.cm. of water were given, and the volume of urine measured every half hour for four or five hours. A normal individual excreted the whole volume in the first hour, no matter what amount had been given. He agreed with other speakers as to the estimation of blood urea and the urea-concentration test. He was also an advocate of the value of estimating the diastase in the urine. Recently he had worked on the question of blood sugar in nephritis, and found that it was raised, whereas normal sugar excretion was diminished.

Dr. W. MacAdam (Leeds) thought that the urea-concentration test was not always reliable in surgical cases. The urea output was occasionally found increased in parenchymatous nephritis or pyelonephritis. Mechanical obstruction interfered directly with kidney function, and was associated with changes in the glomeruli.

Dr. D. W. Patterson (Newcastle) spoke of his experience with men invalided as the result of war nephritis. In most cases renal function had recovered, but cardio-vascular changes suggested that permanent damage had been done to the kidney. He agreed as to the usefulness of the water, urea-concentration, and diastase tests.

Dr. R. Errington (Sunderland) had worked along the lines suggested by Prof. Maclean and had obtained satisfactory results. He relied generally on the urea-concentration and diastase tests, and had found they corresponded in 85 per cent. of 1000 cases.

Demonstrations.

Protein Skin Tests in Asthma.—Dr. Mackenzie Wallis demonstrated the cutaneous reactions obtained in asthmatics with various proteins. He had grouped several closely related types of protein together and combined them into six tests; for example, all the various animal proteins including epidermal, fur, feathers, &c., were used together. If a positive skin reaction was obtained, the particular type of protein causing this reaction has then to be determined separately. After cleansing, the skin was scratched just sufficiently to break the surface without producing bleeding. A positive reaction was shown in a few seconds by a zone of hyperæmia, spreading outwards from the area tested. This was followed by a definite urticarial wheal. In many cases of asthma, the patient was found to give positive reactions to one or more groups. The largest proportion of cases reacting to these skin tests were found to be sensitive to pollens. In the animal group of proteins, feathers appeared to be responsible for the most cases. Care had to be taken to avoid too severe a reaction in a highly sensitive person, and the tests should not be done immediately after an acute attack.

Renal Function Tests.—Dr. Wallis also demonstrated microchemical methods for the estimation of urea in blood, sugar in blood, and sugar in urine. These methods possessed the advantage that they could be easily applied without any inconvenience to the patient. The small quantities of blood required could be obtained by a simple prick of the finger. The blood could either be weighed by absorbing it on a specially prepared filter-paper and weighing on a torsion balance, or the blood could be drawn up into a small graduated pipette. The blood was extracted with distilled water and estimations of urea and sugar made upon the extracts. The use of a tungstic acid method of precipitation of blood proteins devised by Folin and Wu in America rendered such observations possible. It was possible to make an estimation of the blood urea and blood sugar in a very short time, and the estimation of the urinary sugar content could be carried out simultaneously. With these methods it was possible within the space of one hour to obtain considerable information which was of value in the diagnosis of renal insufficiency.

PATHOLOGICAL MUSEUM.

A notable feature of the meeting was the collection of specimens arranged in the College of Medicine by Dr. A. D. Bernard Shaw, secretary of the Pathological Museum Committee. Material had been asked for under the following headings: (1) Exhibits bearing on discussions and papers to the various Sections; (2) specimens and illustrations relating to any recent research work; (3) instruments relating to clinical diagnosis and pathological investigation; (4) individual specimens of special interest or a series illustrating some special subject.

Some very fine exhibits were lent by the Pathological Museum of Durham University, from among those recently added by the curator Mr. W. E. M. Wardell. A remarkable series consisted of groups of specimens illustrating the pathology of individual cases. All the more important blood diseases were thus represented. On one table, for instance, were placed the spleen, liver, heart, glands, and bone marrow from two cases of myelogenous and of lymphatic leukæmia respectively. Together with each set of organs was appended a history and description of the patient. In the same way were shown pernicious anæmia (here a portion of the liver had been treated to show the Prussian blue reaction for siderosis), lymphadenoma, status lymphaticus, and an interesting case of exophthalmic goitre in a discharged soldier. The two latter were placed side by side to emphasise the lymphoid overgrowth in both. A case of pyæmia following osteomyelitis in a child was similarly arranged. The femur showed septic infection of the shaft with separation of the epiphysis of the great trochanter, and was surrounded by the heart, showing acute infective endocarditis, and the lung, kidney, and intestine containing septic infarcts. Next to it was a case of blood infection by the streptothrix of actinomycosis; the primary lesion was in the lung and pleura. The honeycombed appearance produced by actinomycosis contrasted clearly with attention to the factor of repeated scratching in the prolongation of any eruption.

Dr. Dore did not agree with Dr. MacCormac in the exclusion of acne cases from the qualification for a pension.

Dr. Heath remarked that in his opinion many of the seborrhœic cases should have been discharged much earlier from the army.

Afternoon Session.

At the afternoon session Dr. Wells Patterson and Dr. S. Thompson demonstrated a series of very interesting cases in the skin department, Royal Victoria Infirmary. 1. Case of hydroa vacciniforme. 2. Case of a diffuse granulomatous non-ulcerated eruption involving symmetrically the whole buttocks and spreading forward between the legs on to the front and inner aspects of thighs in a middle-aged man. This condition had gradually extended from its commence- ment about the perianal region four years previously. Several areas showed slight scarring after treatment with acid nitrate of mercury while the greater part of the eruption in appearance suggested warty lupus. No biopsy had been made for histological examination, and the Wassermann reaction was negative. The general impression was that this condition was probably lupus, while the suggestion of a fungoid granuloma was also put forward. 3. Case of extensive florid lupus involving buttocks, thighs, lower part of abdomen with lesions on penis, and elephantiasis of penis and scrotum in a man aged 21. The condition had commenced in early childhood. 4. Case of middle-aged man with extensive erythema involving greater part of the trunk and upper third of both arms of ? four years duration, and with no subjective symptoms. Over the back and front of the chest the erythema appeared diffuse, while on the flanks and arms discrete, pinhead-sized, raised lesions predominated. One condition had originated over the upper part of the pre-sternal region and had gradually spread to the present extent. There was no scaling, nor scarring, with some slight suggestion of general thickening of the skin. The general feeling of members was that the condition was probably that of angioma serpiginosum, though a tentative diagnosis of parakeratosis variegata was also suggested.

SECTION OF UROLOGY.

Friday, July 22nd.

The first meeting of the new Urological Section was held on July 22nd, Mr. J. W. Thomson Walker, President of the Section, in the chair, when papers were read by Mr. J. F. Dobson (Leeds General Infirmary) and by Dr. Alfred Parkin (Newcastle) on the

Diagnosis and Treatment of Cystitis.

In introducing his subject, Mr. Dobson laid stress on the unsatisfactory condition of affairs in the treatment of cystitis. This was in all probability due to inaccurate diagnosis and failure to recognise the fact that inflammation of the bladder was frequently secondary to a focus of infection elsewhere in the urinary tract. The first step in diagnosis was the examination of the urine, and the second an investigation of a catheter specimen. After having obtained a bacteriological report on the latter, a careful clinical examination must be undertaken, including a rectal examination in the male, and a rectal and vaginal examination in the female. In the abdominal examination a search should be made for signs of bladder distension or tenderness, also for the presence of abdominal tumours, appendix lesions, prolapse, tenderness, or enlargement of the kidneys. If no explanation of the infection were obtained, an X ray examination must be made of the whole urinary tract for the presence of calculi; finally cystoscopy must be undertaken in order to obtain accurate knowledge of the condition of the bladder and ureters.

In discussing treatment, Mr. Dobson reviewed the urinary antiseptics in general use. Although urotropine occasionally gave excellent results, against these successes must be placed innumerable failures. The ideal compound would be one that was "chemically stable and relatively non-toxic and non-irritating. It should be antiseptic on high dilution in urine of any reaction, and should be eliminated unchanged in high percentage by the kidney" (E. G. Davis). Unfortunately no such drug was at present known. In discussing bladder lavage, Mr. Dobson regarded it of little avail as a prophylactic, but of use as a preliminary to the surgical treatment of enlarged prostate, stricture, tumour, calculus, &c., the action in such circumstances being probably largely mechanical. Renal lavage had become a popular remedy, but unfortunately it appeared that recurrence was by no means uncommon. It had been demonstrated that collargol when used for this purpose permeated the whole kidney and even appeared in the peri-renal fat. More information must be obtained on this subject before a definite opinion of any value could be given. Vaccines appeared to be of very little if any use in the treatment of urinary infections. In the opinion of the speaker the best advice that could be given in this connexion was the following: "If you must have a vaccine, have it prepared by a bacteriologist who is sceptical of the value of vaccine therapy."

Dr. Parkin said that in no branch of his work was a general physician so dependent on the help of a specialist as in genito-urinary cases. For accurate diagnosis the aid of experts in the use of the cystoscope and ureteral catheter, and of a bacteriologist was essential. From an examination of the urine and from a consideration of the symptoms an opinion might be formed as to the site of the disease and of its nature, but without the help of the exact methods of examination employed by the genito-urinary surgeon a reliable diagnosis could not be made with certainty. As a matter of every-day practice cases were met with in which nephritis had been diagnosed because of the presence of albumin in the urine, but in which a more careful examination of the urine showed that the diagnosis was pyuria rather than albuminuria. For this reason a microscopic examination of the urine should be made in order to determine the presence of pus or of renal casts. There were certain cases of chronic nephritis that might easily be confused with surgical conditions of the bladder and kidney, owing to the occurrence of periodic attacks of hæmaturia. The absence of œdema and of albuminuria between the attacks of bleeding in these cases, which are of a granular kidney type, admitted little possibility of error. On the other hand, some acute cases of *Bacillus coli* pyelitis closely resembled acute nephritis, but a mistake would not be made if a careful examination of the urine had been undertaken, and pus cells discovered.

Dr. Parkin concluded by again pointing out the importance of supplementing a careful clinical examination by a bacteriological examination of the urine, and by a skilled investigation of the urinary tract.

The papers were discussed by Mr. A. Fullerton (Belfast), Mr. J. Swift Joly (London), Mr. Kenneth Walker (London), Mr. A. N. Fletcher (Brighton), Mr. F. K. Smith (Aberdeen), Mr. Angus Macdonald (North Shields), Mr. S. G. MacDonald (London), Mr. Thomson Walker, and Mr. W. Clay (Newcastle).

Mr. Clay then introduced the subject of

Contusions of the Kidney.

As a result of having seen two fatalities following the adoption of the expectant treatment of renal injuries, Mr. Clay was in favour of exploration in all cases except those in which the trauma had been obviously of an extremely trivial character. When at the exploratory operation the kidney was found to be severely damaged, and yet doubt was felt as to the justification of immediate nephrectomy, the compromise could be adopted of retaining the organ on the surface. In such a position the kidney was under complete control and hæmorrhage could be satisfactorily dealt with should it occur. He had treated several cases by these means and had been satisfied.

In the second part of the paper Prof. Hill described the method of using the apparatus with modifications for recording the electric changes in a contracting muscle. He found that in normal individuals 40 or 50 vibrations per second were recorded, but that in the case, e.g., of an old man, the record showed obvious tremors. His explanation of this was that in a contraction of the muscle not involving intense activity of the muscle some fibres only were in a state of contraction, and that these fibres were in a state of maximal contraction, obeying the "all or none" law. If the contraction was maintained there was a switching over to another set of fibres. In a healthy individual this switching over was so well coördinated that it occurred with perfect smoothness as shown by the curve. In fatigue or old age it was accompanied by tremors.

In the discussion the President and Dr. W. Martin took part.

The second paper was by Dr. W. R. Grove (St. Ives) and Dr. H. W. C. Vines (Cambridge), on

The Ætiology and Treatment of Varicose Ulcers.

Dr. Grove said that in these cases there was a deficiency of ionised calcium in the blood, and intramuscular injections of calcium were tried. When improvement occurred it was found to be associated with a diminution of the calcium deficiency. Later thyroid extract and calcium were given by the mouth with negative results, except in one case, which showed a marked advance. This suggested the possibility of a contamination with parathyroid, and future cases were treated with parathyroid extract, which, especially in early cases, caused remarkably rapid improvement. Since it has been suggested by the authorities on the subject that the parathyroid gland controls the calcium metabolism of the body, these results indicate that parathyroid deficiency may be the primary cause of the varicose ulcers and explain the beneficial effect of parathyroid extract. In cases of gastric ulcer improvement also followed on the parathyroid administration.

The third paper, on

Anaphylatoxin,

was read by the President, who said, in substance: It is generally agreed that anaphylaxis is due to the formation of an antibody which combines with reinjected antigen. One theory attributes the symptoms caused by the reinjection to the occurrence of this combination in the cells. According to this view antibody in the blood is protective. The other theory supposes that union of antigen and antibody causes the formation there of a toxic substance—"anaphylatoxin." Many methods of imparting such toxicity to guinea-pig's serum have been found, most of them having little direct relation to anaphylaxis. Dale and Kellaway have investigated the nature of the change taking place in serum when it has been rendered toxic by incubation with starch, agar, &c. They find no evidence of protein cleavage, nor any change of viscosity or of surface-tension corresponding to the appearance of the toxicity. "Anaphylatoxin" does not act directly on plain muscle, as it should in theory, but by producing changes in the blood resembling the changes which precede clotting. An animal can be rendered immune to "anaphylatoxin" by a sub-fatal dose, and its serum will transmit the immunity to another guinea-pig; but this guinea-pig, if previously anaphylactic to an antigen, retains its sensitiveness unimpaired. Excess of antibody added to the saline bath in which anaphylactic plain muscle is suspended will protect it from the effect of the antigen. The author regards the similarity of the symptoms produced by "anaphylatoxin" to those of the true anaphylactic reaction as superficial and misleading, and adheres to the theory which attributes anaphylaxis to antibody located in the cells.

The proceedings terminated by a short paper from Prof. M. C. Potter (Newcastle) upon

Certain Electrical Signs of the Human Body.

He described experiments showing that an E.M.F. was produced during the action of yeast on a solution of glucose. He demonstrated a negative charge in the breath exhaled in the human subject.

In the afternoon Dr. G. A. Clark gave a demonstration on "The Passage of Sulphate through the Cells of the Tubules of the Kidney of the Frog." The aorta was perfused with oxygenated Ringer, and the renal portal vein with Ringer containing 0·2 per cent. sodium sulphate. The urine formed contained sulphate.

THURSDAY, JULY 21ST.

Dr. H. Muir Evans (Lowestoft) gave a paper on

Poison Organs and Venoms of Poisonous Fishes.

He described the position and histological structure of the poison glands in the spiny dog-fish, sting ray, and weaver. Specimens of these types were shown and microphotographs of the poison glands and surrounding tissue shown. The slides from which the microphotographs were taken were on view in the Museum. He described his experience of the effects of the wounds inflicted by the fish and the result of the poison. In the case of the wound inflicted by the weaver, one symptom is acute pain, such as to cause the sufferer to express the wish to have the part amputated. Immediate alleviation is obtained by the local subcutaneous injection of 5 per cent. potassium permanganate.

The second paper was by Dr. J. Sim Wallace (London) on

The Physiology of Oral Hygiene.

He emphasised his view that the saliva was of greater value in connexion with oral hygiene than as a digestive juice. He disputed the importance usually attached to the ptyalin of the saliva and attributed its importance to the secretion of mucus, which he considers effective both in protecting and cleansing the teeth.

In the discussion which followed the paper he pointed out that yellow teeth had a thin covering of enamel, and white teeth a thick covering, but that yellow teeth were less liable to decay. He was opposed to the view that imperfect development of the teeth is due to lack of fat-soluble A in the diet.

Prof. C. H. Browning (Glasgow) was unable to be present, but sent to the President his paper on "Recent Work on Chemo-therapy."

A demonstration was given in the afternoon by Prof. Potter of the E.M.F. produced by the action of yeast on glucose.

SECTION OF DERMATOLOGY.

THURSDAY, JULY 21ST.

At the meeting of the Dermatological Section, with Dr. J. Farquhar Christie, President of the Section, in the chair, the morning session was devoted to the reading and discussion of three papers.

Dr. George H. Lancashire (Manchester) read a paper on

The Association of Skin Tuberculosis with Visceral and other Tuberculous Manifestations.

He suggested that the discussion should be concentrated on the practical point. How far is a subject of primary cutaneous tuberculosis liable to secondary visceral infection? The other side of the question—i.e., the secondary invasion of the skin from primary visceral disease—was much simpler and would include the following forms of cutaneous tuberculosis—scrofulodermia, verruca necrogenica from auto-inoculation, acute miliary tuberculosis of the mucous orifices, post-exanthematic dissemination, and the tuberculides. With regard to the tuberculides, the bacillary theory was now being more favoured than the toxic theory. Concerning the question for discussion, any evidence would be only statistical and presumptory, and the literature on the subject was somewhat scattered and fragmentary. Continental figures showed a high incidence of visceral—mainly pulmonary—tuberculosis, many of these with a fatal period which followed. The authors noted that hæmolytic streptococci were widely disseminated amongst carriers, and point out the serious danger attending the treatment of measles.

In conclusion the authors see no reason for assuming that the late pandemic differed in essentials from that of 1890. The bronchial and pulmonary complications, though varied, were characteristic of the epidemic; the influenza bacillus was practically always present, pneumococci and streptococci being found as secondary organisms in the complications. Pneumonia following measles was almost coincident with that following influenza, and there seemed to be little doubt that the influenza epidemic played an important part in the production of pneumonia after measles.

A short appendix deals with a small series of experiments made on monkeys. Two animals into whose nose and pharynx *B. influenzæ* was introduced showed a "self-limited disease resembling many cases of influenza."

A TEXT-BOOK OF MEDICAL JURISPRUDENCE AND TOXICOLOGY.

Fourth edition. By JOHN GLAISTER, M.D., D.P.H. Camb., F.R.S.E., Professor of Forensic Medicine and Public Health in the University of Glasgow. Edinburgh: E. and S. Livingstone. 1921. With 137 illustrations and one coloured plate. Pp. 918. £1 10s.

SIX years have passed since Prof. Glaister edited the third edition of his valuable work on medical jurisprudence, and with the help of a few judicious excisions he has managed to keep the added matter necessary for its re-issue within the limits of about 40 pages. The additions responsible for the increase in the present volume include fresh information relating to industrial and other poisonings, and to lunacy law and responsibility for crime, the case of Arthur Beard occupying six pages. Beard was the man who ravished a girl when he was drunk, and, in trying to smother her cries, killed her. The final appeal to the House of Lords, and the elaborate exposition of the relation of drunkenness to other forms of mental derangement, in connexion with the question of responsibility, will make Beard's case for long the authority in this particular branch of criminal jurisprudence. However, to anyone who studies the legal aspects of mental derangement in its various phases, there is as yet no assurance of finality in the decisions of the courts as to responsibility, nor any promise that Prof. Glaister will not have to include fresh cases of equal importance in his next edition. The prominence given to toxicology in its relation to medical jurisprudence on Prof. Glaister's title page, accompanied by the assignment to this subject of more than a quarter of the space at his disposal, is, of course, fully justified by the importance of the science of poisons in the regions where medicine and the law are brought in contact. It is no part of the medical man's duty to play the detective, except in so far as to do so is to safeguard the life or health of his patient, but in the matter of poisoning the detection of crime may of necessity go hand in hand with the diagnosis and treatment of illness. Suspicion may prove baseless on investigation; but that is no reason why suspicion should not enter the mind of the medical attendant, or be dismissed without inquiry.

In connexion with poisons, as with mental derangement, intoxication, and crime, new editions of text-books dealing with medical jurisprudence will continue to be necessary, and so complete and methodical a work as Prof. Glaister's will have to be kept up to date. It need hardly be said that his index is full and satisfactory, and that his footnotes supply references which will enable his readers to turn readily to the authorities upon which his text is based. His chapter on "Personal Identity" supplies a good deal of useful information, including an explanation of the processes and organisation connected with classification and identification by finger-prints. This is not strictly a medical subject, but is closely linked up with the study of identification by the medical man, who may at any time be called in where finger-prints fail to supply the necessary clue. The monstrous mis-identification of Adolf Beck in 1896, and again in 1904, with John Smith, convicted and imprisoned in 1877, would never have been allowed to pass unchallenged if a medical man had been assigned the duty of comparing the physical facts plainly observable in Beck with the recorded description of Smith. As it was, the police and the female victims of Smith, by perfectly honest mistakes, sent an innocent man in 1896 into penal servitude, and nearly succeeded in doing so again in 1904.

ARTIFICIAL LIGHT.

Its Influence upon Civilisation. By M. LUCKIESH, Director of Applied Science, Nela Research Laboratory, National Lamp Works of General Electric Company. University of London Press, Ltd. London: Hodder and Stoughton. 1921. Illustrated with photographs. Pp. 366. 12*s*. 6*d*.

ARTIFICIAL light is so inextricably interwoven with human activities and has exerted such a profound influence on human civilisation that we gladly welcome, from the pen of an American author and man of science, this readable volume, which is well adapted for the purposes both of the specialist and general reader. It sketches vividly, and with not too much detail, the progress of light and lighting from its infancy to its vigorous youth at the present time, dealing with the accelerated applications during the last two decades. The early chapters describe primitive artificial light—e.g., the art of making fire, and the ceremonial use of light. The real science of light production was born in the latter part of the eighteenth century, and consecutive chapters treat of oil lamps, early and modern gas lighting, electric arcs, and incandescent filament lamps. The next chapters concern the various economic influences of artificial light, and discuss lighting of streets and lighthouses, artificial lighting in warfare, and signalling. Photography, the means of modifying artificial light, the influence of light on health, and spectacular lighting all come in for mention. Finally, we have short chapters on the expressiveness of light, lighting of the home, and lighting as a fine art. With the discovery of fire early man obtained a power over darkness and the vicissitudes of climate, and thereby initiated one of the greatest strides along the highway of human progress. With the discovery of artificial light man's activities were no longer bounded by sunrise and sunset; enormous industrial developments followed the increase of working time.

The possibilities of artificial lighting seem infinite. Even when mankind was well conversant with the advantages of daylight, it took a decade and more of propaganda, not to speak of air-raids, to convince a conservative people that daylight saving was an economical proposition, the needs of the majority being considered. It is interesting to find that long before the late Mr. Willett launched his plea for dayling saving, Benjamin Franklin, in 1784, wrote and published in the *Journal* of Paris, a "seriocomic" essay on daylight saving.

JOURNALS.

Brain. Vol. XLIV., Part 1.—J. Boeke: The Innervation of Striped Muscle-Fibres and Langley's Receptive Substance. The paper contains the results of recent investigations on the mode of innervation of the striped muscle-fibres, the mode of ending on them, the manner in which the nerve endings are connected with the muscle-fibres, and the path by which the stimuli arriving by the nerves may reach the contractile substance of the muscle-fibre. The old conception of the tissues as being built up of cells, which are indivisible, self-propagating, independent organisms originating in a direct line from the dividing egg-cell must be abandoned. In place of it we find the cells he thought, unquestionably due to streptococcal infection. In his opinion those cases associated with tuberculosis were possibly really examples of Bazin's disease. In urticaria and angio-neurotic œdema—the commonest cutaneous reactions in cases of protein sensitisation—the eruption was, in some cases at any rate, a true anaphylactic phenomenon. While perhaps most cases of chronically recurring urticaria were due to food-protein idiosyncrasies, there was nevertheless a very important group of cases—sometimes with angio-neurotic symptoms and in women often associated with symptoms of hyperthyroidism—in which the toxic agent was evidently bacterial. The association of eczema with protein sensitisation and focal infection was now definitely established. Concerning eczema due to external irritants, such irritants may be either protein or non-protein substances, as in "baker's eczema," and that due to paraphenylendiamine in hair-dyes. The phenomena of idiosyncrasy towards drugs, chemicals, &c., and towards proteins were so similar that they might all be conveniently termed anaphylactoid. There were two main types of infantile eczema. The one form corresponding to the true seborrhœic eczema of adults was apparently associated with excessive carbohydrate feeding. The second form corresponding to Czerny's exudative diathesis group was probably always due to susceptibility towards one or more foreign proteins usually of food substances, though in a few cases the offending protein might be bacterial. Eczema of adults was less likely to be often due to food sensitisation but some were directly or indirectly due to focal infection, especially oral sepsis, and more particularly the eczema of the "nummular" type. With regard to lupus erythematosus, in none of the cases which he had investigated was there any evidence of active tuberculosis, but every one of them presented one or more definite foci of infection, especially oral and tonsillar sepsis. From some of his cases he had been able to recover *Streptococcus longus* from the fæces. An important feature of his series had been the accompaniment of the disease by definite arthritis. In the time allotted to him he was unable to discuss the herpes group of dermatoses or alopecia areata. In conclusion, he believed that the further study of individual peculiarities towards foreign proteins and bacteria was likely to solve some of the dermatological problems remaining unanswered.

Dr. CRANSTON LOW described experiments carried out on himself with the artificial production of sensitisation to primula by scarification, which experiments suggested not a local but a general sensitisation. He believed in the influence of heredity. Obviously there was some chemical substance in the different members of a group able to produce local reactions of varying intensity in sensitised subjects. This property of ability to react appeared to lie in and to be confined to the epithelial cells of the skin, in support of which belief were Bloch's skin-graft experiments. Test reactions to food protein were of very doubtful value owing particularly to the occurrence of periods of desensitisation, and in connexion with this part of the subject he would advocate the rubbing of the supposed sensitising substance into the unbroken skin after Moro's method rather than by scarification. He discriminated between urticaria and eczema—the one was a general vaso-motor effect, the second was an effect of skin sensitisation. In Edinburgh Hebra's prurigo was fairly common, often associated with asthma and eosinophilia, but dieting had no effect on this condition. He suggested that the patient by scratching might become sensitised to his own tissues. Dermatitis herpetiformis might be provoked by eating meat and with pemphigus might depend upon the absorption from the bowel of anaphylaxis-producing substances. With regard to lupus erythematosus he considered that Dr. Barber's experiments were in the right direction, but he personally had not seen any focal reaction to vaccines. In acute infections such as typhoid fever hypersensitisation always preceded immunity, while in chronic infective conditions the period of hypersensitisation might persist indefinitely.

Dr. HALDIN DAVIS was unable to follow Dr. Barber the whole way. All the various cutaneous irritants caused their own individual reaction in each case. In his opinion the exudative reactions were due to bacterial proteins. Focal sepsis was very common in any class of affection, dermatological or other.

Dr. KENNETH WILLS asked what definition of eczema should be adopted in the consideration of this question of sensitisation. Should the follicular type of infection in infants—associated with dry pityriasis capitis in the parents or nurse—be classed as eczema and was it due to protein sensitisation, or again the cases of the erythemata due to light occurring on the exposed parts of elderly patients?

Dr. BARBER replied, drawing attention to the presence of indicanuria in some cases of eczema excited by light.

Dr. CRANSTON LOW referred to eczema due to light and to the hæmatoporphyrinuria occurring in cases of hydroa vacciniforme, and suggested that the circulating hæmatoporphyrin (a hæmolytic substance under the influence of light rays) was the cause rather than an effect of this condition.

Dr. HENRY MACCORMAC read a paper on

Skin Diseases in Pensioners.

Our meagre knowledge of the ætiology of so many skin diseases occurring under ordinary circumstances made the question of the pensioner's claim a particularly difficult one. For resolving the problem into a less complicated form he suggested classifying all these cases as far as possible into three groups: i. Where the disease is definitely due to war service; ii. where it is open to question how far war service may have caused or aggravated the complaint; iii. where the condition should not be attributed to war service. Group i. would include all diseases of parasitic origin such as oriental sore, scabies, infected tuberculosis of the skin, and ringworm. Even at the present time pensioners presented themselves with conditions labelled scabies which had taken origin during the war. Some of these were instances of dermatitis due to the prolonged application of sulphur, others had been incorrectly diagnosed as scabies—for example, cases of dermatitis herpetiformis. This group should also contain two other classes: (*a*) Where the disease had arisen or become chronic owing to the impossibility of obtaining some special recognised form of treatment, and (*b*) where the remedial measures employed had resulted in disfigurement or injury. Group ii. comprised conditions such as eczema, psoriasis, and lichen planus. The assessor must be prepared to answer two questions: (1) If the condition had arisen during service, was it attributable? (2) If it had existed prior to this, how far had service aggravated it? Seborrhœic eczema was peculiarly prevalent among the troops in France—ranking third in incidence (from figures from No. 25 General Hospital, B.E.F.), after the two recognised infections of scabies and erythema—so that it would seem to have been directly connected with the conditions of army life there. If we considered eczema merely as a symptom of some underlying dyscrasia, a view which was not unsupported by facts, then might we not conclude that the abnormal state, of which the eruption was only a part, had resulted from a condition attributable to service? The rule of conceding that any first attack was attributable to service, and that a skin disease known to have existed during civil life, and which reappeared due to service had been aggravated by it, seemed equitable and just. Group iii. included conditions such as acne vulgaris and self-inflicted eruptions. Many youths who had entered the army were of the acne age-period, and there was no evidence that the circumstances of military life contributed in any way to cause this affection. Concerning the self-inflicted conditions, there was always the difficulty of obtaining the proof.

Dr. CRANSTON LOW maintained that each case must be considered on its own merits—e.g., a first attack of psoriasis had followed vaccination in the army, commencing on the vaccination site. He would draw if workers take unnecessary risks and if safety appliances are not used; and (*d*) to discuss accidents which occur, their causation and means of prevention. Signs are clear that welfare constantly needs coöperation with medical advice; this is well shown in the account given in the June number of a successful medical conference held at the London headquarters of the Industrial Welfare Society. The conference was attended by medical men engaged whole or part time by industrial concerns. Addresses given by Dr. R. M. Wilson and Prof. E. L. Collis are shortly reported; both speakers dwelt upon the importance of industrial hygiene and upon the value to industry of medical supervision. The conference appointed a small committee to consider the position and report to an adjourned meeting which is to take place in September at Balliol College, Oxford.

Journal of the Royal Army Medical Corps, July, 1921.—In this issue Sir William Leishman lifts a corner of the covering veil to tell how the enteric fevers were prevented in the late war. Typhoid fever had been a serious matter in South Africa, but preventive inoculation had diminished it, so inoculation, albeit voluntary, became a recognised service proceeding, and it was decided that, in the event of a mobilisation, inoculations would be more freely offered, vaccine would be sent to the depôts in quantity, and increased manufacture of vaccine would be at once begun. As it was planned so it happened: indeed better, for Lord Kitchener himself recommended inoculation to the soldiers in orders. Those who went overseas were ever better and better protected; 30 per cent. in the original expeditionary force, but 90 to 98 per cent. before long. Clinical differentiation of the enteric fevers is difficult, so these cases were all primarily classed as "enteric suspects," and later diagnosed by the laboratories, rigidly, as typhoid or paratyphoid A or B, the remainder were termed "enteric group." It soon became clear that inoculation was worth while. In 1915 the average British force in France was 613,000, the inoculated were 94 per cent.; they showed 0·94 cases per 1000 and 0·056 per 1000 deaths, the uninoculated 6 per cent. had 7·64 cases and 2·306 per 1000 deaths. In the first 16 months of the war the protected British had some 170 deaths, the French 11,690. The French later took to inoculation and became as immune as the British. Sir William Leishman ascribes escape from typhoid fever to (1) preventive inoculation; (2) field sanitation; (3) exclusion of carriers (in itself a laborious series of researches). Triple vaccine (T.A.B.) was introduced in February, 1916. The thorough laboratory work done on the "enteric suspects" made easier the early differentiation of the hitherto unknown trench fever.

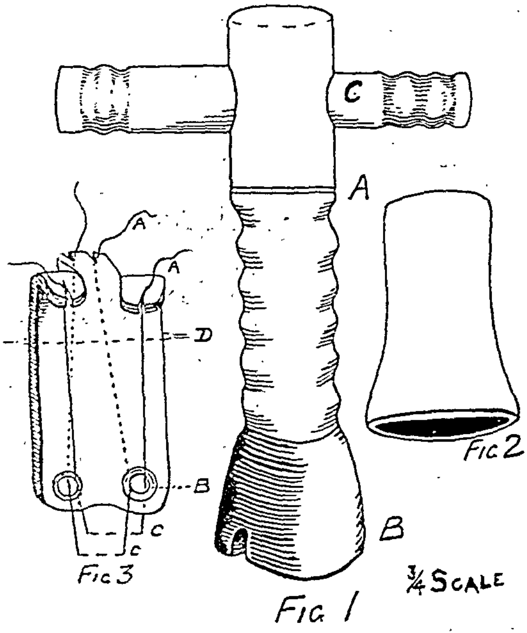
Colonel W. F. Tyndale, writing of the work of an A.D.M.S., shows that the greatest anxiety of a medical staff officer with an army in the field is the evacuation of wounded during an action, and he tells in illuminating detail how this may best be done. Dr. W. Wallace, in "The Vision of the Soldier," has some excellent and sympathetic remarks on the origin, prevention, and treatment of malingering. A labour unit was sending up many eyesight malingerers. One who had vision 6/60 only, was slowly induced to admit 6/6. "Do you know who I am?" said the ophthalmologist. "Some sort of medical officer," said the malingerer. "No," said the medical officer decisively, "I am a detective," and eye cases from that unit at once fell off.—Dr. Melville D. Mackenzie, assistant port medical officer of Liverpool, reports that sporadic typhus outbreaks in the front line in Mesopotamia were best dealt with by simultaneously delousing the whole infected party, and this by dropping kit and clothing into boiling water with a little alkali for 1½ minutes; all lice and eggs are killed. The method is quick, sure, and attainable. A question occurs to us. If a man's clothes are damaged by this procedure, has he any claim for compensation? His life has probably been saved. Disinfection has damaged, we suppose, his clothes. Without the disinfection his death would have precluded his using them.

London Panel Committee Gazette.—The last number of this circular for insurance practitioners in London gives a useful account of the Drug Fund and of the various changes which have taken place in the Regulations framed to control this fund. The rôle of the panel committees is clearly set out along with certain rules for their guidance, which are the result of considerable experience. Practitioners may well note the definition of excessive prescribing and the object of Article 34 of the Medical Benefit Regulations.

New Inventions.

IMPROVED DEVICES FOR BLADDER DRAINAGE AND CLOSURE.

THESE devices have proved to me very satisfactory. Fig. 1 is an improvement on the suprapubic drainage-tube previously described in THE LANCET (May 11th, 1918). The oval bulbous end, B, plugs the bladder wound and prevents leakage after a purse-string suture is applied above it. Leakage, however, is usually caused not only by not using such a device but on account of the bladder wall shrinking away from the parietes. Hence some surgeons sew the edges of the wound of the parietes. The trumpet end holds the bladder up, but I wind the sutures C C, Fig 3 (about to be described), round the arms C of Fig. 1. If a rubber drain be preferred, the head is separated at A and driven into the rubber tube. Fig. 2 is an oval tube, which, if pushed into the bladder end of the rubber, will fulfil the same use as B, Fig. 1. Oval bladder tubes are best. Fig. 3 shows the little device to which I would draw particular attention. It is easily made in a few minutes. Its object is to close the bladder wound when this is no longer required, thus hastening convalescence and preventing fistula. C C show the sutures inserted on each side of the bladder wound; the ends of these, as before mentioned, are temporarily tied round the arms of Fig. 1. When this tube is removed these ends are crossed through holes B of Fig. 3 and brought into slots as shown. The edges of the bladder wound are thus closely brought together and heal before the super-imposed tissues. D shows skin surface.



J. MACMUNN, M.R.C.S., M.R.C.P.I.
Finsbury-pavement, E.C.

Mr. MACDONALD discussed the treatment of bladder growths. The treatment of choice in cases of papilloma was diathermy applied through a cystoscope. Unfortunately such treatment had serious limitations; growths low down in relation with the internal meatus were mechanically impossible to reach, while some growths increased in size so rapidly that it was difficult to keep pace with them. Single papillomata in patients over 45 to 50 years of age should be subjected to operation rather than to diathermy, as it was impossible to tell with the cystoscope whether any given papilloma was malignant or benign. The only satisfactory treatment of carcinoma of the bladder was excision, but unfortunately about 50 per cent. of cases were inoperable before they reached the surgeon. For this reason special emphasis must be laid on the importance of early diagnosis and of cystoscopic examination in all cases of hæmaturia.

The PRESIDENT gave an account of the

Open Operation for Removal of the Prostate.

He pointed out that the complications that might be feared after prostatectomy were: (1) hæmorrhage; (2) post-operative infection; (3) post-operative obstruction. Many deaths ascribed to shock were in reality the result of hæmorrhage. In other cases, although hæmorrhage might not be entirely to blame, it contributed largely to a fatal result. Cases of obstruction following prostatectomy were by no means rare. The obstruction in such cases generally lay at the internal meatus where the bladder opened into the cavity left after removal of the prostate, and was due to the semilunar fold formed by the trigone muscle and the overlying mucous membrane. In order to avoid these complications and sequelæ, for several years he had practised the open operation, thus bringing the operation of prostatectomy into line with other modern surgical procedures. In order to obtain a good view of the bed from which the prostate had been removed, the patient should be placed in the Trendelenburg position and a special bladder retractor employed. Any strips and folds of mucous membrane left after enucleation of the prostate must be picked up with long forceps and clipped away. After trimming and removal of these folds a large oval opening was left at the vesico-prostatic orifice which fully exposed the interior of the prostatic cavity. The suggestion had been made that the mucous membrane at the internal meatus should be stitched to the urethral mucous membrane, but such a refinement was unnecessary even if it were practicable. What was necessary was to make certain that loose folds, tags, long shreds, and small detached gland nodules were not left hanging from the wall of the cavity to promote sepsis and encourage the formation of secondary stone by sloughing. The operation, as well as diminishing the amount of sepsis and the risk of post-operative obstruction, also allowed of the complete control of hæmorrhage, any spouting vessel being seized by means of forceps and tied. Two objections had been raised to the open operation—namely, the length of the incision and the increase in the time required for completion of the operation. However, these objections were not of great moment, for the operation could be completed within 20 minutes, and the risk of post-operative hernia was not increased by the larger incision.

In the afternoon a joint meeting was held with the Section of Radiology and Electro-therapeutics, at which large numbers of excellent skiagrams of calculi were exhibited. Dr. ROBERT KNOX, President of the Section of Radiology, gave an account of work done on the subject of biliary calculi, whilst Mr. THOMSON WALKER showed some excellent pyelograms and photographs of calculi of the urinary tract.

WALLASEY SANATORIUM COMMITTEE.—This committee, which has been in existence eight years, terminates its activities this year; its work is to be transferred to the Town Council. Over 100 cases have been dealt with during the period named, only 4 per cent. of cases coming from Wallasey village itself.

Reviews and Notices of Books.

EPIDEMIC RESPIRATORY DISEASE.

By EUGENE L. OPIE, FRANCIS G. BLAKE, JAMES C. SMALL, and THOMAS B. RIVERS. London: Henry Kimpton. 1921. Pp. 402. 36s.

THE sub-title of this book—The Pneumonias and Other Infections of the Respiratory Tract Accompanying Influenza and Measles—is really a better guide to its contents than is the actual title. The volume is the outcome of an exhaustive inquiry into epidemic respiratory disease occurring amongst American troops at Camp Funston (Kansas) and Camp Pike during the period covered by the late influenza pandemic. It does not pretend to give any information as to the pandemic as it occurred in other parts of the world or as to epidemic respiratory disease in general, and nearly all its references therefore are American; but as a record of lobar pneumonia, broncho-pneumonia, purulent bronchitis, &c., occurring in an army of healthy young adults under military training the book is of considerable value. Intensive studies of this kind make for accuracy, and we wish that there had been more opportunity for such work amongst the British armies in the field.

The masses of statistics and pathological and bacteriological records need no further précis than they receive in the excellent summaries at the end of each chapter. The book may be roughly divided into two parts, the one dealing with the influenza epidemic and its pulmonary complications, the other with measles and its complications. With regard to the former the authors conclude that Pfeiffer's bacillus is the "specific etiologic agent of epidemic influenza" and that it is always present in early uncomplicated cases, a point of view that is now gaining ground. An investigation of normal individuals showed a rapidly increasing prevalence of the bacillus simultaneously with the progress of the epidemic, raising thereby a consideration of the carrier condition which the authors believe is, in influenza, analogous to that found with other infections. They hold that if "*B. influenzæ* is to be regarded as the cause of influenza it must change quite rapidly under certain circumstances from a relatively saprophytic organism to a relatively virulent pathogenic organism, and conversely return to its avirulent state following the passage of an epidemic." Pneumonia following influenza presented a complicated picture; the bacteriological results with the "typing" of pneumococcal strains showed 12 per cent of types i. and ii., and 88 per cent. of the other types found in normal mouths (type ii. atypical, iii., and iv.). These results are remarkably similar to those obtained in Edinburgh by Dr. W. R. Logan, whose paper in the May number of the *Edinburgh Medical Journal* was recently reviewed in these columns, though we are not quite clear as to whether or no the identical methods of classification were used by the American author and Dr. Logan. The American authors also note that no definite evidence could be obtained that Pfeiffer's bacillus alone caused pneumonia. Here again the results agree with those of Dr. Logan. The hæmolytic streptococci were apparently rarely found in the Edinburgh inquiry, whereas in the American epidemic they were not uncommon. In America great difficulty was experienced in obviating secondary infections with this variety of organism, and the authors point out that absolute elimination of overcrowding in the wards, segregation of patients according to type of bacterial infection, and effective individual isolation are all essential measures in prevention.

The measles epidemic followed, and was therefore complicated by, the influenza epidemic. Altogether 867 cases of measles were observed, amongst which there were 56 cases of pneumonia and 48 of otitis media. Hæmolytic streptococci were rarely found during the pneumonia period, which occurred early in the epidemic, but were common during the otitis

8. Persistent indigestion in middle life, with loss of weight and change of colour, may mean internal cancer.

This knowledge will save lives, and should be brought home to the public, for the plain facts about cancer are not generally known. Cancer theories and cancer cures have their fascination for the curious, but nothing can exceed the usefulness of making what is now known of cancer a commonplace in every household in the country.

◆

Anoxæmia in Clinical Neurology.

In an address given to the British Association in 1920, and published in The Lancet in August of that year,[1] Dr. J. Barcroft dealt with some of the medical aspects of oxygen-want, or anoxæmia. Its importance as a factor in the production of symptoms in disease is as yet but incompletely defined. This may be because we are not very familiar with its clinical manifestations, which, therefore, are not readily recognised. Dr. Barcroft clearly indicated the circumstances in which we may expect anoxæmia to occur, and defined three types of the condition. These are (1) an anoxic type, due to low oxygen tension in the blood, such as occurs at high altitudes and when for any reason lung ventilation is imperfect; (2) an anæmic type dependent upon a deficiency of hæmoglobin in the circulation, as in anæmia, or in carbon monoxide poisoning when much of the hæmoglobin is not free to take up oxygen; and, finally, (3) a stagnant type, when, with a normal blood, the supply to the tissues is defective. However produced, the cells in these circumstances lack sufficient oxygen for their metabolic needs. Quite apart, therefore, from those special atmospheric conditions applying to aviators and miners, there must surely be a variety of common affections owing some part of their symptomatology to this physiological factor. What this part may be, how often present and how important, it remains for clinical investigation to tell us. Nowhere is its influence so clear as in the case of the nervous system, and it is with this aspect of the problem that Dr. F. M. R. Walshe deals in an article on the Rôle of Anoxæmia in the Production of Symptoms in Disease and Injury of the Nervous System in the current number of *Medical Science*.[2] The results of experimental physiology indicate that the initial reaction of the central nervous system to minimal grades of oxygen-want is the development of a true hyper-excitability. Indeed, the extreme sensitiveness of the nerve cell and the synapse to oxygen deprivation has long been a commonplace of physiology. Though directed to other ends, numerous and diverse observations on the reactions of the spinal animal have attracted the attention of physiologists to this factor. Kaya and Starling and Mathison found that asphyxial states owe their effects mainly to anoxæmia and not to the carbon dioxide excess which accompanies it. Normally, spinal transection induces a state of shock in the divided cord which precludes all reflex activity, yet in slight asphyxia the acute "decapitate" cat may show apparently spontaneous scratch reflexes. Even after extensive posterior-root section motor discharges continue, indicating a true hyper-excitability of the spinal grey matter. A complex reflex response, comparable with the "mass reflex" described by Head and Riddoch in spinal man, may be obtained in the cat after shock has passed off, and its occurrence is of importance in the light it may throw on the origin of this phenomenon in man.

Of wider clinical interest are the psychical and neurological symptoms of cerebral anoxæmia. Haldane has said that "anoxæmia not only stops the machine but wrecks the machinery," the machine in this case being the brain. However, Barcroft produces evidence showing that acute anoxæmia of short duration probably leaves no residual defects of function or of structure behind it. The complete recoveries observed during the war in some cases of the superior longitudinal sinus syndrome of Holmes and Sargent, in which the motor cortex is asphyxiated severely for a period of hours, confirms this view. Nevertheless, though they are but transient and possibly of rare occurrence, such symptoms are not without significance to neurologists. They include impairment of the highest cerebral functions; defects of memory, of attention, and of judgment; marked emotional disturbances, such as pugnacity, extreme irritability, and the presence of fixed ideas. On the lower levels we see tremors, ataxy and weakness, increase of tendon jerks, muscular twitchings and spasms, and subjective and objective sensory disturbances. The symptom-complex of tetany may be readily produced in the normal subject by an artificially induced anoxæmia. Of chronic anoxæmia, as Barcroft has pointed out, we know very little, and it is this form that we might expect to be of more frequent occurrence and of greater significance to clinicians. On the whole, the symptoms seem to resemble those of fatigue rather than those of irritation which characterise the acute forms. The whole question is clearly one of which there is urgent need of further knowledge. Walshe emphasises the importance of quite another aspect of the problem. At the moment, phylogenetic and more particularly psychogenetic factors are being widely invoked to explain the genesis of disorders of the nervous system. Highly speculative theories of both orders abound and bid fair to eclipse a physiological method of approach to the problems of disordered function in the nervous system. Phylogenetic hypotheses are rarely capable of proof and as rarely find support in comparative anatomical or physiological studies. Further, it is urged that physiological factors must first be eliminated before we can justifiably seek a psychical origin for nervous diseases. Moreover, a sound knowledge of neuro-physiology should be regarded as an essential part of the equipment of the psychologist attacking any problem of clinical neurology. That this does not always obtain is seen from the frequent confusion of physiological and psychological categories seen in the writings of psychopathologists. In a recent book on this subject, a highly elaborate psychological theory is built up on the basis that skeletal muscle tone is innervated from the autonomic nervous system. Yet this is a postulate not accepted by physiologists and one with a great weight of direct evidence against it.

The wide range of psychical and somatic nervous disorders which may arise from a simple physiological factor, such as anoxæmia—and there are doubtless others as important—should therefore make us pause before we abandon lightheartedly the physiological method which has so brilliantly advanced our knowledge in the past and has been one of the proudest boasts of the English school of neurology, in favour of abstract and speculative psychological methods. It is only by the combined labours of trained workers in both fields, and not by the facile and exclusive adoption of any single method, however new and attractive, that progress will be made.

[2] F. M. R. Walshe, Medical Science, 1921, iv., 427.

derived by division of the egg-cell at some period of development fusing to form a syncytium, from which the adult cells are later differentiated. The adult cells are thus independent of the old ones, and by this means the "individual dominates the elements which compose it," and harmony between the different tissue elements is achieved. This is found to be the case in the nervous system and the "neurone theory" requires revision. Further, the fibres of the neuroblasts do not run free in the interstices between the cells, but everywhere they follow distinct protoplasmatic paths, either of migrant medullary elements or of mesenchymatous cells, until they reach their destination. During the process of nerve regeneration, after a nerve has been cut, there exists, or is established, a perfect harmony between the elements of the different tissues which build up the path that has to be followed by the regenerating nerve-fibres. By means of special preparations it is shown that in both striped and unstriped muscle-fibres the nerve fibre axis-cylinder passes through the sarcolemma and ramifies in a layer of granular protoplasm which is collected in a small mass at the place of the nerve ending. In the sarcoplasm surrounding the neurofibrillar end-ramifications there is a reticular differentiation, extremely delicate, on one side attached to these ramifications, on the other side losing itself in the sarcoplasm. This Prof. Boeke proposes to to call the "periterminal network." It is difficult to say whether it is to be regarded as a continuation of the neurofibrillar structure or as a differentiation of the sarcoplasm itself. The author does not hesitate to assert that it is of sarcoplasmic origin, but he considers that it develops only in connexion with and under the influence of the neurofibrillar structure of the nerve ending. After section of a motor nerve it rapidly disappears, and as soon as the regenerated fibres reach the muscle-fibre the periterminal network reappears. The author believes that it represents the "receptive substances" of Langley. With regard to sensory nerve endings, at least two different kinds of tactile end-organs exhibit the same feature. The corpuscles of Grandry in the skin covering the duck's bill consist of two large flat disc-like cells within a capsule, with the axis-cylinder terminating in a flattened expansion between the cells. In Bielschowsky preparations not only could the tactile disc be seen in a syncytial connexion with both cells, but inside the protoplasm of these cells there was visible a distinctly stained, sharply defined network in absolute continuous connexion with the neurofibrillæ of the tactile disc. Therefore there is reason for supposing that not only in the case of the motor endings but also in the different forms of the sensory nerve endings there exists in the first place a close connexion between the nerve endings and the surrounding "lemmoblastic" elements that gives us a right to speak of a syncytial arrangement; secondly, we may assume that everywhere between the neurofibrillæ of these nerve endings and the protoplasm is inserted a distinct reticulum, which seems to be the histological substratum for the receptive substance of the physiologists.

F. J. F. Barrington: The Relation of the Hind-Brain to Micturition. Having previously established that (1) there is a motor tone passing to the bladder through the pelvic nerves which arises in the central nervous system above the level of the lower thoracic region of the cord; (2) transection of the cord in the lower thoracic region abolishes reflex micturition—i.e., the reaction which ultimately occurs if a bladder is gradually artificially distended, leading to the expulsion of its contents; (3) transection of the cord in the lower thoracic region permanently abolishes micturition; the author endeavours firstly to determine the level in the central nervous system of the origin of the motor tone of the bladder muscle; secondly, to find out what parts of the central nervous system could be removed and micturition still take place; thirdly, to find what simple reflexes are combined together to form micturition. It was found that the tonic influence the central nervous system exercises on the bladder through the pelvic nerves arises at about the level of the middle of the pons. The conclusion appears to be justified that reflex micturition takes place normally in cats in the absence of the whole of the fore-brain and anterior part of the mid-brain. It is probable that removal of the cerebellum has no effect on reflex micturition. Experimental analysis of reflex micturition showed that active contraction of the bladder can be produced by distension of the organ to a given volume, by slightly moving the catheter in and out in the direction of the urethra, and, lastly, by distension of the posterior urethra. Two reflexes were found leading to relaxation of the urethra; they were evoked respectively by running water through the urethra and by distending the bladder. It appears that these five reflexes are of such a nature that when one starts the others are brought into action automatically. It is noted that five to ten minutes after decerebration passage of urine by a forcible stream very commonly occurs. This appears to be due to the removal of an inhibitary influence arising in the part of the brain removed.

Cecil Worster-Drought: Lesions of the Posterior Tibial Nerve. Lesions to this nerve are most frequently overlooked. The motor disability is relatively slight, the patient complains of pain or numbness in the foot; it is seen that he is able to plantar-flex the foot at the ankle and also to flex the toes. As a result, the condition is often termed "functional." This happened in many of the 64 cases which form the basis of the communication. Changes in cutaneous sensibility are found over the sole, at the margins of the foot, and over the posterior and lateral aspects of the heel. There is also paresis and often atrophy of the plantar muscles and interossei, the toes being hyper-extended at the metatarso-phalangeal joints and flexed at the inter-phalangeal joints. When the site of injury is above or involves the branches of the posterior tibial nerve supplying the flexor longus hallucis and flexor longus digitorum muscles, flexion of the toes is either much diminished or is entirely absent. The ankle-jerk is also reduced or impossible to elicit. The author advocates exploration of the nerve when sensory disturbances of long standing are the predominant feature.

The number also contains a summary of a paper on Tabes: Its Early Recognition and Treatment, by Dr. Farquhar Buzzard, in which he draws attention to the value of the recognition of the character of lightning pains, and a paper on the Effects Produced by Obscuring the Vision of Pigeons previously deprived of the Otic Labyrinth, by Mr. Sydney Scott, both being read before the Neurological Section of the Royal Society of Medicine.

The Journal of Industrial Welfare (Monthly. Price 9d.) continues to keep us posted with the way in which the welfare movement is advancing, notwithstanding the vicissitudes through which the world of industry has been, and still is, passing. This publication continues to improve and has now become well established. An excellent article, well illustrated, appeared in the March issue from the pen of Mr. W. B. Welch, of the Birmingham Small Arms Company; attention is drawn in it to works notice-boards, to the advantage of having an arranged scheme of notices, and to the need for making them attractive. From time to time matters of definite medical interest are discussed, as, for instance, when Major J. B. Malone in the May number described an excellent scheme put in force by the Portland Cement Manufacturers, Ltd. The essentials of the campaign are: (1) the education of the workman by propaganda; (2) coöperation between employees and management; (3) "safety first" committees in the works; (4) watching for hazards; and (5) encouraging suggestions. These essentials are pursued with encouraging results by the committees whose duties are (*a*) to encourage "safety-first" principles amongst the workers; (*b*) to report to the management likely hazards and methods for minimising them; (*c*) to report

Annotations.

"Ne quid nimis."

PROFESSIONAL SECRECY.

We understand that certain of our readers have concluded from a sentence in a leading article which appeared in The Lancet of July 23rd, that we urged the General Medical Council in the exercise of its powers with regard to infamous conduct in a professional respect to remove from the Register the name of any practitioner who gave evidence against a patient in a court of law, whether ordered to do so by the judge or not. We did not make any so direct recommendation, and the motive of a purely tentative suggestion has been misunderstood. In a brief reference to the discussion at the meeting of the British Medical Association, we wrote: "As it is, the lawyer and the priest are not protected by statute, but no one questions the lawyer as to what the prisoner has told him and *the priest would be punished for divulging. Possibly* the General Medical Council *might assist* by offering to remove from the official register the name of any practitioner who laid bare his patient's secrets on the invitation of a judge." This was intended to convey, and in our opinion was only calculated to convey, the suggestion that, at present, the often referred to case of the Roman Catholic priest offers no parallel to that of the medical man. If the former enjoys any special privilege or protection in the witness-box, as to which we are sceptical, it is due to the belief (1) that he has solemnly pledged himself not to reveal the secrets of the confessional; (2) that he would incur ecclesiastical penalties by so doing. We consequently suggested that as no such pledge or penalties exist for the doctor, his refusal to give evidence might "possibly" be strengthened by his being able to point to the danger that he would incur in giving it. We frankly agree with one correspondent that the High Court of Justice might resent such action on the part of the General Medical Council. The mention of what "possibly" might be done was, however, a suggestion only. It was made in accordance with the view developed in a leading article in The Lancet of July 30th, that at some future date a test case calculated to arouse a strong combined protest by the medical profession, should call attention to the whole subject. Moreover, the suggestion, as another correspondent has pointed out to us, was made at the meeting of the British Medical Association.

THE INTERNATIONAL ASPECTS OF CHILD WELFARE WORK.

An informal conference on the International Aspects of Child Welfare Work was called by the Friends' Relief Mission in Vienna on July 18th. The honorary president was Frau Marianne Hainisch, mother of the President of the Austrian Republic. Miss K. D. Courtney acting as chairman in the morning and Dr. Hilda Clark in the evening. Other speakers included Prof. von Pirquet. Miss Jane Addams, president of the Women's International League for Peace and Freedom. Dr. Poerner, and Dr. Horneck, as well as representatives of child welfare agencies in Switzerland, France, Austria, and Germany. The value of relief work in promoting international understanding was dwelt on by several speakers. Dr. Hilda Clark pointing out that, while international legislation was vitally important, the interest and goodwill of ordinary people, especially of those concerned with questions of family life, might have far-reaching effects in the economic welfare of nations. Miss Jane Addams advocated an international standard of child welfare below which no country should go, which would prevent children from starving in one country while abundant food was available in an adjacent one. Prof. von Pirquet, dealing with the incidence of tuberculosis in Vienna, said that, while it had been very prevalent before the war, the years of under-nourishment had given it a terrible impetus. It had been found that 90 per cent. of the children examined reacted to the cutaneous test, and as soon as symptoms of tuberculosis declared themselves in an individual it was necessary to take active steps to increase the powers of resistance. Prof. von Pirquet described the means taken to supplement the insufficient sanatorium accommodation in Austria. The roof of a hospital for tuberculous children had been adapted to take 100 patients, who thus spent their whole time in the fresh air, the beds being placed under a roof shelter. By this simple and inexpensive device the accommodation of the hospital had been doubled, and remarkably good results had been obtained. Dr. Poerner said that, whereas diseases of the digestive tract formerly accounted for the greatest number of infant deaths, general debility now ranked first as a cause of infant mortality, suggesting an embryonic weakness resulting from bad health conditions in the parents. The decrease in digestive disorders was mainly due to the fact that, owing to the scarcity of fresh milk, a far greater proportion of mothers nursed their babies than in pre-war days, in spite of their own under-nourishment. Pyæmia and skin diseases showed an increase as a cause of death, while a falling-off in nervous diseases might be accounted for by a reduced consumption of alcohol on the part of parents.

THE TEACHING OF OBSTETRICS AT LEEDS.

The Leeds Maternity Hospital is one of the youngest and most useful of the Leeds charities. Founded in 1905 by the Leeds Ladies' Hospital and Maternity Fund, it began its work with 33 beds; in 1910 the hospital was transferred to the present buildings, which are well situated and not far from both the medical school of the University and the infirmary. There are now 70 beds, and material enlargement is needed. During 1920 the number of patients treated at the hospital was 1540; of these 1314 were cases of confinement, the balance being made up of cases attended elsewhere, in which complications had arisen as a direct result of labour. In addition to the work done within the walls of the hospital, there is an extern department in which, last year, the number of confinements was 1366. Five subsidiary homes are maintained in connexion with this extern department; the managers of the hospital have from the first recognised the importance of the teaching of midwives as a part of their work, and during the year 98 pupil midwives received training, 83 obtaining the certificate of the Central Midwives Board. In connexion with the training of nurses at the General Infirmary an arrangement has been made by the board of the infirmary for 20 of the infirmary nurses to receive three months' training at the Maternity Hospital, so that they may obtain the midwifery certificate. To carry this arrangement out the infirmary grants to specially selected nurses scholarships which cover fees and expenses during training. Nurses are also received for training from the Poor-law infirmary, from the West Riding Nursing Association, from the general infirmaries at Halifax and Nottingham, and from other institutions. The work is under the control of the members of the honorary staff, of which the Professor of Midwifery at the University is an ex-officio member.

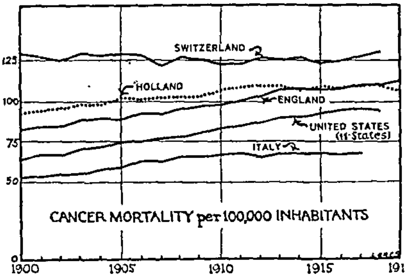
The presence of this well-equipped hospital in Leeds has enabled some great improvements to be brought about in the instruction of students; prior to 1885 the latter had to rely on the private practitioners for their experience in practical midwifery, while a few went to special institutions such as the Rotunda. At the request of the board of the medical school an extern maternity department was instituted at the infirmary; after some years the desire for more systematic teaching in practical midwifery led to some few cases of special difficulty being admitted to the infirmary, and subsequently a very small intern

THE LANCET.

LONDON: SATURDAY, AUGUST 13, 1921.

Cancer and the Public.

TUBERCULOSIS, as we pointed out last week, shows signs of being a moribund disease. Cancer, on the other hand, appears to be renewing its youth. The bills of mortality due to cancer have been rising year by year in most countries of Europe since exact figures were available; the increase has been variously ascribed to more exact diagnosis, the introduction of tomatoes to the diet, and a lack of opportunity of dying of other diseases; but, explain it how we will, the sinister fact remains that each year more deaths from cancer in this country are recorded. We are glad therefore that Red Cross organisations are taking note of this fact and regarding it as a field for voluntary effort. The June *Bulletin* of the League of Red Cross Societies contains a striking article on the importance of early treatment in cancer, supplied by the League's department of medical information. Intensive work is going on in many parts of the world to seek out the essential cause or causes of cancer—much of this work has been recorded in our columns—but for the moment nothing has arrived of proved utility in preventing or curing the disease. At the same time, as the *Bulletin* justly indicates, the cure of cancer offered by the surgeon is more certain to-day than any cure which the phthisiologist has to offer to the tuberculous, for all his acquaintance with the bacillus of Koch; and it is suggested that the Red Cross societies of the world have a great field of service for their propaganda of knowledge among the peoples.



The *Bulletin* sets out nothing that is not well known to medical men and women, and even to the well read of all classes. But this is not enough when we recall that in 1919, to take an example, 4151 British women died of cancer of the womb, of the majority of whom it may be said with confidence that operation undertaken in the earliest stage of the disease would have ensured their recovery. Out of every 100 women who come to consult the doctor with this complaint, 60 are already in so serious a condition that no operation can be attempted; for 20 more an operation is attempted too late to stop the encroaching disease; 5 die as a result of operation which is serious in itself when left to the last moment, and only 15 are cured. The immediate solution of the problem may be expressed in one word—Educate. Here is work for Red Cross societies if they want it—namely, to teach the public that to wait until cancer causes pain is to wait for death. If a woman over 35 years of age suffers from irregular bleeding, especially after intercourse, she should at once consult a doctor. Some may shrink from doing this from motives of modesty, but there are now many medical women and there is a hospital staffed entirely by women doctors in South London. The *Bulletin* paints cruelly but truly the result of neglect of this earliest indication of serious disease.

Let us suppose that the early symptom is neglected; how then does the illness progress? A sudden severe loss of blood may occur and by alarming the patient may also save her life. Or there may gradually develop a constant discharge, at first watery, then more deeply stained with blood, finally evil-smelling, thick and yellow. The patient is beginning to lose weight and at any moment she may feel the first gnawing of pain—the pronouncement of a sentence from which there is seldom, if ever, a reprieve. The pain grows worse, the wasting becomes extreme, until the sufferer lies helpless in bed, too weak to move, nauseated by the evil stench from which her nostrils will never again be free, unable to eat or sleep, and racked by an incessant torture, until death comes as the only friend potent to release her.

It is truly a terrible picture; none who have witnessed it can ever forget it, but it is not an uncommon picture. Radium may do something sometimes, morphia may help a little at the end, but knowledge, if it is given to the people in time, can save these lives and all this suffering.

This is only an illustration; the same can, of course, be said in regard to cancer of the breast and other visible cancers. The medical profession knows all this too well. The crucial matter is to get the knowledge into the hands of the public. The American Society for the Control of Cancer has long been educating the American public in this way and has prepared a list of facts about cancer that might well be published broadcast.

1. Cancer begins as a small local growth which can often be safely and easily removed in the early stages by competent surgical treatment, or in certain favourable cases by radium, X ray, or other methods.

2. The beginning of cancer is usually painless; for this reason its onset is doubly insidious, and other danger signals must be looked for and heeded in time.

3. Cancer is not a constitutional or blood disease and there should be no thought of disgrace or hereditary taint associated with it.

4. Cancer is not a contagious disease and there is no danger from living in the same house or from contact with a patient.

5. In ordinary sense, cancer is not inherited. Some authorities believe that there may be inheritance of a certain tendency to the disease, but even this is not clearly established. The disease is so frequent that, by the very law of chance, many cases will occur in some families. Life insurance companies do not regard cancer in the family as a reason for rejecting applicants or increasing premiums.

6. A persistent lump in the breast, or continued abnormal discharge or bleeding should take a woman to her doctor forthwith. The increased flowing which frequently occurs at the change of life is always suspicious, as is the return of flowing after it has stopped.

7. Sores, cracks, lacerations, lumps and ulcers which do not heal, warts, moles or birthmarks which change colour or appearance are danger signs which demand competent medical investigation and treatment.

the low flats—all necessitate careful consideration. For use on the reservation the water is pumped to settling tanks, where the suspended matter is first precipitated by coagulation with aluminum sulphate, after which the water is passed through sand filters. This purification is further supplemented by disinfecting the water with liquid chlorine. Mosquitoes, it is noted, have been practically exterminated by the usual methods. The reservation offers many facilities for research work, particularly in various phases of sanitary engineering. Its position is suitable for the establishment of a school for the teaching of public health administration.

THE FUTURE OF RED CROSS CLINICS.

SCATTERED over the country are a number of clinics founded by the Red Cross for the treatment of the wounded. Now that pensioners under treatment are happily becoming fewer, a movement is being made to retain the services of these clinics for civilian patients. Physical therapy in the treatment of injury and disease is becoming more and more widely recognised, and there are comparatively few large city hospitals where a department devoted to this treatment cannot be found. But the expense of securing this treatment in private is considerable, and a large section of the community is rightly unwilling to attend hospital for treatment, and yet cannot afford to pay for it to be administered privately or in their own homes. For these the proposed transfer of the Red Cross clinics to civilian work will be an incalculable boon, and may well be carried through provided sundry safeguards are observed. We may classify these briefly as affecting the medical men of the district, the patient, and the practising masseur. Little opposition will arise from medical men provided that patients are admitted to the clinics only on the recommendation of a qualified medical practitioner. This would protect the clinic from the patient who casually drops in for treatment without the knowledge or consent of his doctor. Patients must be safeguarded by placing the clinic under the care of a medical man specially qualified to prescribe details of treatment, and able to supervise and control everything that is done on their behalf. The interests of the practising masseur should be safeguarded by ensuring that only patients who are unable to pay the fees for private treatment usual in the district are received as patients of the clinic. This would entail the employment of an almoner or some other person suitably skilled in social service work. Should the clinics be run in any sense as competitors with the private masseur, great hardship would be inflicted. Granted these safeguards, we welcome the proposed transfer.

TUMOURS OF THE BONY CHEST. WALL.

ACCORDING to Dr. C. A. Hedblom,[1] of the Mayo Clinic, tumours of the bony chest wall are comparatively rare. He has collected 213 cases, including 48 from the Mayo Clinic, 23 of which came to operation, and 25 in which operation was not performed. In 167, or 78·7 per cent. of the 213 cases, the tumours were of the ribs, and 46, or 21·3 per cent., were of the sternum. 61·4 per cent. were sarcoma, and 18 per cent. were chondroma, the ribs being primarily involved in 78·7 per cent., the sternum in 21·3 per cent. Of the Mayo Clinic cases, 2 were examples of recurrent carcinoma following amputation of the breast in the female, in 2 the primary growth was in the male breast, 1 was a hypernephroma secondary to a tumour of the kidney on the same side, and 1 was secondary to a cancer of the thyroid. Although there is usually no history of trauma in tumours of the chest wall, the absence of such a history is no proof that the origin of the tumour was not traumatic. Minor injuries, as Dr. Hedblom points out, are as a rule quickly forgotten. Moreover, chest tumours are commoner in males who are more liable to injury, and the area involved is usually the more exposed anterior and lateral portion of the chest. It is probable therefore that in some cases at least trauma plays a part in the ætiology both with regard to incidence and the malignant degeneration of the benign forms. Apart from the presence of a tumour, pain, which may be present before there is any discernible growth, is the most characteristic symptom both in benign and malignant tumours, being present in 50 per cent. of the 213 cases. Loss of weight was noted in 15, or 31·2 per cent., dyspnœa was present in only 4 cases, and effusion in 2. In typical well advanced cases the diagnosis of neoplasm is certain, but in early cases a diagnosis may be impossible. Cold abscess, exostosis, gumma, aneurysm, and dermoid cyst must be differentiated. Early radical extirpation, which was performed in 10 of the 48 Mayo Clinic cases, is the treatment of choice, while late radical or palliative extirpation, which was performed in 13 of those cases, may result in a relatively long period of freedom from recurrence even in the presence of extensive involvement. The contra-indications to operation are metastases, very extensive involvement, periostitis, and advanced cachexia. Intratracheal or intrapharyngeal insufflation anæsthesia affords an effective means of preventing operative pneumothorax. Shock, pneumonia, and empyema are the commonest causes of death following operation.

STOCK ALLEGATIONS AGAINST INSURANCE DOCTORS.

AT the recent delegates' meeting of the High Court of the Ancient Order of Foresters, held at Leeds, serious charges were made against panel doctors. In the words of the High Chief Ranger, as they appear in the daily press:—

1. Panel doctors frequently issue certificates without seeing the insured person.
2. There is a marked tendency...... to refer patients for hospital treatment as out-patients, as the panel doctor gets his capitation fee whether the man is well or ill. The net result is that the doctor draws the money while the hospital does the work.
3. In some cases panel doctors show a reluctance to call on patients outside surgery hours.
4. In order to retain their panel at present strength "a few" panel doctors are chary about offending possible malingerers by giving them too hasty clearing-off notices, fearing that the patients might change their panel.

Items 1 and 4 refer to breaches of the certification rules and the Order of Foresters has only itself to blame if the doctors guilty of such unprofessional conduct are not brought before the proper tribunal. Lax certification is dealt with very severely by the Minister of Health when cases are brought to his notice by medical service subcommittees, and the General Medical Council has warned the profession that such conduct will incur grave penalties. In regard to item 2 the practice of referring cases to hospital out-patient departments is necessary under the present system owing to the fact that in no other way can a second opinion be obtained for an insured person. That hospitals are not paid for the services they render to insured persons is not the fault of the insurance practitioners, who hope that the omission will be rectified in the near future. The reluctance suggested in item 3 would render doctors liable to a charge of negligence, also a matter readily dealt with by the medical service subcommittee. It seems to us that there is little or no substance in these and similar complaints, for, as Sir A. Mond pointed out in the House of Commons last week in reply to Mr. Haydn Jones, machinery is provided under the Insurance Act regulations for investigating complaints and imposing penalties where such complaints are substantiated. But the Minister added that he was considering whether the time had not come for an inquiry into the working of the Acts as regards both cash and medical benefits.

---

Mental Hygiene.

WE publish this week, in an abridged form, the important address delivered by Dr. C. HUBERT BOND before the Medico-Psychological Association at the recent annual meeting of that body. Dr. BOND is not only President of the Association, but a Commissioner of the Board of Control, and these facts might well have deterred him from independence or originality in his remarks: but, as will be seen, his double responsibilities produced the exactly opposite effect upon him. He spoke clearly, he spoke out, and was ready with a constructive policy, making no attempt to conceal shortcomings, but facing the truth that considerable reform is necessary in directions to which he makes specific reference. There is little if any support to be found in the address for the sensational views adopted by certain newspapers which delight to picture lunatic asylums as prisons, but there is no suggestion that the circumstances which surround the treatment of mental patients are ideal either for the patients or for the medical staff. Dr. BOND shows clearly that these circumstances are not calculated to promote the mental hygiene by which the beginnings of mental disease can be prevented and recoverable cases put in the way of recovery. And most thinking people will agree with him.

The subject is just now very much before the public. It is dealt with in some detail in the annual report, just received, of the Scottish Board of Control, where a series of recommendations may be found for setting up psychiatric clinics on the basis of 30 years' experience of observation wards in Glasgow. It should be borne in mind, say the Scottish Commissioners, that at the present time skilled advice and treatment of incipient insanity form the prerogative of persons sufficiently wealthy to afford it, and that the vast majority of the people can only receive treatment for insanity after the malady has become so confirmed that they can be certified and placed in asylums. We reviewed last week two books upon the administration of lunatic asylums, one written by Dr. MONTAGU LOMAX entitled "Experiences of an Asylum Doctor," and the other, "A Mental Hospital," by Dr. JOHN MACARTHUR, medical officer at Colney Hatch. There is no comparison between the two authors in the matter of experience; from Dr. MACARTHUR we get a detailed picture of the administrative side of mental medicine from one who is specialising in his subject; while from Dr. LOMAX we get a vivid sketch of the life that has to be lived by the inmates of mental hospitals, both patients and their curators, written as the result of a temporary if protracted charge. It will be allowed, however, that more than occasionally the man who is *in* a department but not *of* it, can take an all-round view of things as they are in a way which is not easy for those bred in the system. He can ask himself and others the why of happenings which normally pass unquestioned as matters of routine and tradition. Dr. LOMAX's criticisms of the conduct of asylums, which in many cases amount to charges of inhumanity in administration—though this may have to be inferred rather than be the subject of categorical statement—are to receive official investigation. Sir ALFRED MOND has now promised in the House of Commons that the visiting committee of the asylum at which Dr. LOMAX was employed as locum tenens will be asked by the Board of Control for their observations upon Dr. LOMAX's statements, with a view to possible action. We hope that there will be a prompt publication of the views of the Board of Control, for there is no factor more potent in keeping early and curable mental cases out of the reach of medical treatment than public distrust of asylum régime.

At the recent meeting of the British Medical Association, before the Section of Neurology and Psychiatry, Prof. G. M. ROBERTSON, superintendent of the Morningside Mental Hospital, read a most interesting paper on the diagnosis and treatment of borderland cases. He defined the borderland as where, on one side of a boundary, we have the region of the neuroses, consisting of disorders presenting such symptoms as spasm, paralysis, and sensory disturbances; and, on the other side of the boundary, the region of the psychoses, which included such disorders as mania, melancholia, and dementia præcox. He points out that between the two sets of conditions no hard-and-fast line can be drawn, the neuroses and psychoses passing gradually from one to the other. This is not a negligible strip of territory, but a stage whereon the most poignant dramas of human life are played, but, owing to public distrust, among other things, the actors receive no medical help, in too many cases, until obstinate conditions of mental ill-health have been developed. All of which brings us back to Dr. BOND's wise pronouncement that mental health is no less important than ill-physique, and that the Report to the Ministry of Health of the Consultative Committees, English, Irish, and Welsh, on the physical health of the community, and how to preserve it, should form a broad model upon which we should strive to preserve the mental health of the people. The numerous barriers which prevent the intelligent treatment of in-patient mental cases should be relaxed, the position of uncertifiable cases requiring mental treatment should not be ignored, for, as Dr. ROBERTSON has shown, the uncertifiable pass into the certifiable, by which time they have become resistant to all treatment. Without the need for new legislation we can progress in the treatment of the out-patient cases; but several things are required. Broader vision from the medical profession and the public, so that they may see mental disease as a disorder logically dependent upon cause and effect, and often curable. Machinery whereby mental cases can be medically treated like sick people that they are. And money.

◆

REGIONAL MEDICAL OFFICERS.

OF the 33 regional medical officers appointed by the Ministry of Health one has died, and the vacancy is not being filled. In making this statement in the House of Commons in reply to a question by Sir JOHN HARMOOD-BANNER, Sir A. MOND stated that these officers act as medical referees on questions of incapacity of insured persons for work referred to them by the Approved Societies, or raised direct by insured persons. In addition they act as consultants to insurance practitioners and generally assist in maintaining the efficiency of the insurance medical service. That should now be common knowledge, and we may hope that the spate of questions on the subject will soon dry up. From the side of the Approved Societies welcome recognition is coming in of the work of the regional medical officers. This appears in the recent annual report of the Prudential Approved Societies, and the societies as a whole are making more use of the new system which is working well. If the insurance practitioners on the other side coöperate with the regional officers it should result in a better understanding between the two main parties in the working of medical benefit, and the insured person will gain from the smooth working of the insurance service. This service may have to be extended shortly in regard to purely consultation cases, for the regional staff has been overworked through the increased number of references occasioned by the coal crisis.

the chemical, bacteriological, and physical qualities of river, well, and reservoir water under remarkable conditions.

Questions of Quality often Ignored: the Example of Toronto.

It is to be regretted that there still remains the tendency to accumulate waterworks statistics without proper consideration being given to the circumstances which govern the safety and potability of the supplies in question, for these are of high value from a comparative point of view. Not long since (1914) an important Blue-book (Return as to Water Supplies—England and Wales) became available for reference. Despite its great use, it is matter for regret that all *detailed* references to the chemical and bacteriological composition of the supplies dealt with are practically ignored. Beyond doubt the returns are filed away and are theoretically still available for inspection, but for the time being, at all events, the facts are buried. Is it too late to plead for their resuscitation, and for an authoritative account of how far the abnormal conditions of drought have influenced our water-supplies throughout the country from a *quality* standpoint ?

In 1919 a paper on Water and Sewage Purification appeared in Reports of the Progress of Applied Chemistry, Vol. IV. In dealing with the valuable work carried out at the Toronto water laboratories, the following observations were made, which are worthy of repetition here, as showing the importance of accumulating accurate data throughout the country as to the qualities of our water-supplies and the need for scientific investigation :—

> "Toronto is splendidly equipped for carrying out important water investigations. A very large number of samples are examined and many valuable researches carried out on water purification, and one can only compare the scale of their operations to that of the Metropolitan Water Board, which have always interpreted Section 25 of the Metropolis Water Act (1902) in the most liberal and imperial spirit, as if indeed their responsibility to humanity was of general and not merely of local significance. Can quite the same be said of all our large water undertakings throughout the United Kingdom? It is to be feared that this cannot be said, but the fault is not to be found with the medical officers of health, analysts, chemists, and bacteriologists concerned, but rather with waterworks authorities who, too often, are content with the little rather than the more, and who do not always recognise that applied science has infinite possibilities, not only as regards safeguarding health, but in respect of saving unnecessary expenditure, and that these matters should be looked upon in a national and not a parochial spirit. It is true, however, that in very many cases the water-supply is so pure that numerous analyses and comprehensive investigations may seem to be uncalled for, and, no doubt, this has influenced waterworks policy in the past. Nevertheless, a great deal can be learnt from the study of even pure water, and there can be but few waterworks which possess no problems awaiting solution by the trained observer."

The Present Need for Strict Economy.

Not within the memory of most, if any, of us, apart from the disquieting remembrances aroused by the Worthing (1893), Maidstone (1897), and Lincoln (1905) epidemics, has the question of water-supply aroused so much interest as in the present year. As a counsel of perfection it is well to plead for supplies unimpeachable at their source and abundant in quantity. But we must be prepared to consider, if not accept, compromises, or to embrace new ideas, or perhaps even to condone temporary expedients, not because we have recklessly abandoned our old principles, but in view of the fact that this time, of all times, is the opportunity for searching diligently, in relation to questions of water-supply, for avenues leading to economy. In matters of this kind it would be a grave mistake to create a false impression. It is not hinted that it is permissible to gamble on the real safety of our water-supplies, but it is suggested that the lessons of the war and its aftermath, and the circumstances arising out of the drought, and increased knowledge generally, have taught us many new things operating in the direction of economy.

Economical considerations have within recent years influenced waterworks procedure.

In 1915 Aberdeen received the assent of Parliament to a scheme for purifying the River Dee for waterworks purposes by (1) excess-liming, (2) short storage, and (3) rapid filtration, the saving in capital cost on alternative schemes exceeding £100,000. The way towards this event was paved by the discovery that caustic lime present in water, in even the smallest excess, exercised a strong bactericidal action.

In 1916 the Metropolitan Water Board decided to save coal by chlorinating raw Thames River water (70-80 million gallons a day) and allowing the treated water to flow by gravity down the Staines aqueduct, instead of first pumping it up into Staines Reservoirs. The difference, for the year ended March 31st, 1921, between the cost of pumping and the cost of chlorinating represented a saving of over £10,000. The New River supply of the Metropolitan Water Board is made up of a variable mixture of New River water (Upper Lea water) and pure well water. During the greater part of the year, owing to the good quality of the well water and the relatively satisfactory state of the river water, the filtered water results are remarkably good, as judged by the ordinary chemical and bacteriological standards, despite the fact that the rate of filtration at the New River works is considerably in excess of that practised at the other works of the Board. During winter floods the river water deteriorates so much that the excellent quality of the well water fails to "mask" the deterioration of the mixed filtered water product. The storage reservoirs at Hornsey and Stoke Newington are far too small to affect the position materially. In 1916 the Metropolitan Water Board started investigations with the object of seeing whether it might not be possible to remedy this state of affairs by chlorination. It is obvious that to increase materially the filtration area, or to provide adequate storage accommodation, would mean an immense capital outlay in order to improve matters during these transitory periods of deterioration.

The experiments have been most satisfactory in a bacteriological sense, and preliminary difficulties as regards taste have been overcome by the use of permanganate and carefully graded doses of chlorine according to the current quality of the water.

In 1917 Rotherham decided on the policy of re-using the abandoned and severely censured Ulley gathering ground, and, subject to the approval of the Local Government Board, to supply from this source water rendered safe by sterilisation processes. Somewhat later Cardiff determined to adopt a similar course in regard to a portion of their gathering ground, which had been provisionally given up as not wholly satisfactory for waterworks purposes.

In 1917 Accra was faced with a very unsatisfactory position as regards its water-supply. The water (swamp water, liable to pollution) deteriorated to a remarkable extent in the relatively large storage reservoirs, absolutely necessary for purposes of quantity. Exhaustive experiments were made, and it was found that by applying the "excess lime" method of treatment the water was freed from excremental bacteria—e.g., *B. coli*—and remained clear, odourless, and free from growths under conditions of storage. The saving on alternative purification works represented a large sum of money. This is the first occasion on which the excess-lime method has been used for the express double purpose of destroying "plankton" development and rendering water safe from the epidemiological point of view.

In 1919 Sheffield conceived a scheme for the utilisation of river water as compensation water, which, despite its bold and unprecedented character, received, with certain reservations, the assent of Parliament. It is of interest to consider this unique proposal at more length, because its influence on future procedures may be far-reaching. Sheffield was obliged by Act of Parliament to pass about 10 million gallons daily of pure moorland water from the Dam-Flask and Rivelin reservoirs down the course of the grossly polluted River Don (which, of course, was not used for drinking purposes) as compensation water. The proposal was to reserve this pure water to increase the domestic supply to Sheffield, and to abstract from the Don below the point where the sewage effluent from the city, together with many other impurities, entered the river an approximately similar amount of water, to purify and soften it, and to pump the purified river water back about eleven miles up-stream and pass it through the statutory mill gauge in lieu of the unnecessarily pure water discharged from the reservoirs for compensation purposes. The word "unnecessarily" in this connexion is used advisedly, for the River Don water was only used for trade purposes and was so heavily polluted with ochre streams, trade effluents, and waste liquors near and below the point of discharge of the compensation water that to "feed" it with water of a high degree of purity was a wasteful procedure. Sheffield considered that if they purified and softened the river water abstracted below Sheffield to a standard at least equal to that proposed by the Royal Commission on Sewage Disposal, and softened it as well, they were in no department was opened at the Hospital for Women, but not until the development of the Maternity Hospital was the present arrangement made possible. The University and the Maternity Hospital have entered into an agreement by which the hospital undertakes the whole of the practical teaching of the students in midwifery. This instruction is directed by a committee, which consists of the Dean of the Faculty of Medicine and the honorary staff of the hospital, including, of course, the Professor of Obstetrics. The University and the hospital combine in the election of a resident medical officer and obstetric tutor; the University regulations require that all students shall attend the intern work of the hospital for a period of one month before doing any duty in the extern department, and from the resident officer the students will receive their earliest practical instruction. It will soon become necessary to appoint a junior to assist in the work. It is very desirable that all students, during the time they are on intern duty, be provided with accommodation close to the hospital so that they may be summoned by telephone to see all cases of difficulty and of interest. Strenuous efforts are being made in this direction, and it is hoped that these will shortly prove successful.

PAYING POOR-LAW PATIENTS IN MANCHESTER.

THE result of conferences between the Manchester Board of Guardians and representatives of the medical profession has been agreement upon a scheme for the use, by paying patients, of beds in Poor-law hospitals. Amongst other provisions of the scheme, which is to be controlled by the medical superintendent of the hospital in which the beds are provided, are the following:—

> The beds shall be available for cases sent in by any medical practitioner who shall be allowed, if he desires, to attend, treat, or operate on them himself, with the assistance of the resident medical and nursing staff of the hospital.
>
> Patients shall be admitted to any of the beds with the recommendation of a medical practitioner, where possible, subject to the final approval of the medical superintendent of the hospital.
>
> Any practitioner may, if he desires, attend and treat gratuitously any patient recommended for admission by him who can only afford the standard hospital fees for maintenance and treatment. Intention to do so must be stated at time of admission.

It is felt by the representatives of the Manchester Medical Committee that the arrangement may not only prove of great value to a number of patients, but will also provide an opportunity for general practitioners to participate in institutional treatment. The tariff of fees will be arranged by the local Medical Association.

COMPOSITION OF HUMAN FAT.

ALTHOUGH a good deal is known regarding the chemical composition of the fatty tissue of animals and its relation to the fats in the food, little work has been done on the constitution of human adipose deposit. It is agreed that the fats of infants have a higher melting point and contain less oleic acid than the fats of adults. In a recent article O. Schirmer[1] describes the results of his investigations to determine whether the state of nutrition and conditions of disease affect the composition of the fats of the human body. He examined the fat of the abdominal wall. It showed extraordinary variation in water content, from 5 to 71 per cent., so that there can be no question of anything like a mean water content of 29·9 per cent. as given by Vierordt. In fat persons the fatty tissue contains less water than the fat of lean individuals, so that there would appear to be a relation, hitherto unobserved, between the fat and water metabolism of the body. From his observations the author concludes that in certain cases of disease very large amounts of fat in adipose tissue are replaced by water, and in this condition the absorptive connective tissue plays an important part, especially as the test tissue which contained most water showed the largest amount of connective tissue. In the fats themselves the consistence diminishes with increase in the iodine number. Fats with a high iodine number—about 70—are fluid at room temperature. On standing there is formed gradually a solid deposit consisting of tripalmitin. In fat individuals the iodine index rises very considerably and the fat is much more fluid than in spare individuals. The amount of cholesterol is much higher in fats with a low iodine number. A normal iodine number in a person of normal nutrition may be taken as 65 to 66·5, corresponding to an olein content of 59 per cent. In very fat persons the corresponding iodine number lies in the region of 70. Tables are given to show the influence of diseases and constitution on the quantity and composition of the fats, but no simple rules can be deduced from them. Nephritis, diabetes, and castration seem to lessen the iodine number. Experiments on rabbits and ducks were undertaken to study the effects of food fats on the body fats. The composition of the fats given in the food modified the composition of the body fats, even when the food contained no excessive amount of fat. The administration of oil increased the iodine number, while tallow diminished it. Human fat with an iodine number of 69 melts at 16° to 20° C., and rabbit fat with the same iodine index at 40° C.

A MODEL VILLAGE IN U.S.A.

THE first annual report on the health department of the model village which the United States Public Health Service has been developing for nearly two years on the 516-acre Government reservation at Perryville, Maryland, contains some interesting information. The reservation was used during the war as a site for a large nitrate plant; the buildings included 200 cottages, two general stores, a model school house, club, firehouse, and theatre for the work-people, and the whole property was handed over by Congress for use as a hospital site and for storage of the medical supplies of the Public Health Service. The Public Health Service promptly transformed a group of cottages into one hospital and set out to build another; the two together now accommodate 430 patients. Not including the variable hospital contingent, the reservation now has a population of 839 persons, the sexes being, roughly, equally represented. The birth-rate on the reservation was 39·33 per 1000, as against 21·30 in the whole State and 28·78 in the county. The death-rate was only 3·07, an excess of children being roughly balanced by the small number of aged persons. While this low death-rate is partly due to the favourable age constitution of the population, much of the credit is laid at the door of the efficient health administration. Careful work has kept down the figures of cases of communicable disease, particularly diphtheria, of which 30 cases occurred during the year in the county and three on the reservation; one of these last was a new-comer, one a young sister of a boy who was found to be a carrier, and one an adult. The low prevalence of contagious disease is ascribed directly to close watch and prompt isolation, laboratory diagnosis, and prophylaxis, and indirectly to pasteurised milk, filtered and chlorinated water, school medical supervision, and good living conditions, including sewers, screens, and covered garbage cans. A physical examination of the children showed that 93·5 per cent. had physical defects of teeth, tonsils, adenoids, eyes, or hearing, this large percentage probably being due to the lack of facilities for remedial correction nearer than Baltimore. Similar percentages are found in the county outside the reservation. Many of these defects have recently been corrected. Between Nov., 1919, and Nov., 1920, the percentage of underweight children was reduced from 42·7 to 13·8. The drinking water is drawn from the Susquehanna River, and is, unluckily, in bad condition, being contaminated in several highly variable ways. The geological formation of the country, the daily conflict of the tide and the river current, and the strong winds on manifesting itself in mortality statistics; for we learn, whereas among grinders in Sheffield for the five years, 1908–12, the average number of deaths due to pulmonary tuberculosis was 58·2 per year, while the deaths from this cause amounted to 51·2 per cent. of deaths from all causes, that in the two years, 1919–1920, the average number of deaths due to tuberculosis was 33·5, while these deaths formed 33·0 per cent. of deaths from all causes. We are glad to note the diminution in tuberculous silicosis in a city where it has been rife all too long.

---

[1] Arch. f. Exp. Pathol. u. Pharmakol., vol. lxxxix., 1921.

Mr. G. S. Ram deals with dangers associated with the use of electricity in factories. He points out that shock from alternating currents at low pressures is more fatal (18 cases out of 25) than from high tension (4 cases out of 20), and stresses the fact that much ignorance as to the importance of artificial respiration still exists even among ambulance men and doctors. No matter how "dead" the victim may appear to be, artificial respiration should be *immediately* applied, and kept up for *at least two hours*, even though the doctor on arrival should rashly pronounce life to be extinct.

The subject of health and sanitation is reported upon by Miss Martindale, who deplores neglect of that short arresting requirement of the Factory Act, "A factory must be kept in a cleanly state." She deplores it in the interests of health and psychology, since the general tendency is for workers to fall into line and become in harmony with their environment. She reviews the conditions found in many industries, and when referring to unnecessary high temperatures, quotes a chance remark, "Bible talks of earning a living by the sweat of the brow—it's done by the sweat of the whole body here."

Progress of Welfare.

Considerable interest attaches to the summary given by Dame Adelaide Anderson of the progress of welfare, progress which makes it certain that the improvements already recorded will steadily spread, largely on the initiative of workers themselves, throughout industry. In this connexion provision of welfare accommodation, such as canteens, and the help of welfare supervisors, are rightly considered to be the forerunners of welfare developments which tend to increase and engender good feelings. Many experiments to meet the particular needs of each works are afoot, and testify to the vitality of the movement in glass works, cutlery and electro-plate works, oil and seed mills, woollen, worsted, hosiery, silk, cocoa-nut matting, and other textile industries, as well as in the metal trades and fish curing; while in a growing number of factories medical women are being appointed to supervise the health of women and girls. In relation to canteens it is found that if they are kept comfortable and clean they are well patronised, thus adding industrial significance to the truth "that unquiet meals make ill digestions." The introduction of washing facilities is reported to be much appreciated; for instance, at one cotton mill, with a long queue of workers waiting to wash at the dinner hour, although the idea of washing-basins had been scoffed at before they were installed, it was found difficult to cope with the numbers who wanted to use them. Here little less than an industrial revolution is proceeding.

When we turn from these matters to first-aid and ambulance, reported upon by Mr. J. C. Bridge, similar rapid advance is recorded. Novelty of treatment by sterilised dressings is passing away, and in a few years first-aid on modern up-to-date lines will become essential to the equipment of every works. Its value can be measured: one large firm of iron and steel manufacturers reduced their annual compensation rate from 17*s*. 7*d*. in 1918 to 16*s*. 7*d*. in 1919, and to 14*s*. in 1920: this result is attributed to avoiding septic cases through provision of first-aid attendance at all hours: elimination of lost time should also be added to the credit side. A picturesque description of sugar-refining is given by Mr. H. J. Wilson, who tells how charcoal filter beds are filled by men only lightly clad, descending through manholes with bags over their heads to the bottom of black, warm cylindrical filters, where they spread the charcoal thrown down to them by treading it level—a dirty and disagreeable operation. A code of welfare regulations is outlined, the establishment of which appears to be badly needed. The subject of factory lighting is reported upon by Miss R. Squire, who is still able to tell of windows in old shops invariably dirty, of walls lacking whitewash, of machines installed without consideration for natural light, while window space is cramped and blocked by stuffed rags and stored materials. Dirty windows and old-fashioned burners are false economy while the sun shines without; illumination in factories clearly lags far behind scientific knowledge.

Medical Research in Factories.

The chapter contributed by Dr. T. M. Legge is of particular interest. It draws attention to the way in which factory doctors are being appointed in large American establishments, a development which is stimulated from within and not imposed by the State from without. Contrast is rendered possible by an account given with the recent development in Belgium where the State has established a complete factory medical service, with a whole-time inspectorate and part-time employment of medical practitioners. Both countries in this matter are well in advance of Great Britain. Dr. Legge reports the result of a careful investigation into the amount of lead present in the air of places where electric accumulators are made; it confirms the conclusion previously arrived at by him, that about two milligrammes of lead inhaled daily represents the minimal dose which will cause plumbism. Continued attention is being directed to the subject of epithelioma among patent fuel workers. Early treatment and medical supervision are now considered able to prevent this disease; but we appear to be no nearer to determining the injurious constituent in pitch which causes malignancy. The subject of industrial dermatitis continues to receive special attention from Mr. Bridge, who holds strongly that, apart from personal susceptibility, personal cleanliness is the all-important preventive. Several interesting inquiries made by him are reported under this heading.

Mr. J. H. Parsons supplies a report on glass-workers' cataract, which commences in the posterior layers of the lens, and also occurs among workers exposed to other molten and red-hot metals. The probability is expressed that this form of cataract results not from the direct action of rays upon the lens itself, but from indirect action affecting the nutrition of the lens through the ciliary body. The rays concerned would appear to be heat rays rather than ultra-violet rays. Prevention can be assured if workers will only wear spectacles of Crookes's glass.

Readers who recall the correspondence in the public press as to the causation of phthisis among printers will welcome the account of an investigation made by Mr. C. B. Roos into the dust of printing shops. The suggestion made that printers suffer from tuberculous silicosis due to inhaling silica dust never had anything except imagination to support it. Now Mr. Roos reports that printing shops contain but little dust, often less than an ordinary room, and that the little dust present contains very little silica, less than is found in London "domestic" dust.

HOSPITAL GRANTS AND WAGES OF EMPLOYEES.—The Secretary to the Treasury was recently asked whether his attention had been drawn to a resolution passed by the public pharmacists branch of the National Drug and Chemical Union, to the effect that no grants from public funds should be made to any hospital or other institution unless the provisions of the fair wages clause were observed in the payment of the employees; and whether he would give effect to this resolution and make the fair wages clause applicable in connexion with the grants to hospitals. The reply was delivered by Sir Alfred Mond, who stated that he had received a copy of the resolution and would bring it to the notice of the Hospitals Commission.

LUNACY AND DIVORCE.

IN the House of Commons recently Mr. Rendall, M.P., asked a question of the Home Secretary as to the number of married persons in lunatic asylums in England and Wales; as to how many of these had been certified for more than five years; and as to the intention of the Government with regard to the recommendation of the Royal Commission, that certified insanity of five years' duration should be a ground for divorce. The figures apparently were not available, and it was intimated that no measure of the kind suggested could be added at present to the programme of legislation. They would be interesting figures if they should be obtained, as they would show roughly how many persons could possibly be affected by the facility for divorce proposed. They would not show with anything like accuracy how many divorces would follow the innovation, for there would certainly be a considerable proportion of men and women who would not avail themselves of it. Such figures, when compiled, should be amplified by particulars as to the respective numbers of the cases in question in which insanity has been established for 10, 15, 20, or more years. In the event of divorce on the ground of insanity being made possible at some future date, it would also, no doubt, be provided only for cases where the patient, according to the best medical opinion obtainable, is incapable either of recovery or of appreciation of the step taken. We do not propose to discuss a question into which personal convictions and personal religious belief enter largely, but we would point out that sympathy for this and other classes of cases of great and admitted hardship has undoubtedly increased in the last few years. This has been largely due to the obvious fact that the existing law is not confined in its action to the cases of cruelty, desertion, and adultery for which it was intended, but is taken advantage of to secure the annulment of many marriages by processes which savour strongly of mutual agreement and collusion. It is naturally argued that if young people who have little or nothing worse than boredom to complain of in their married lives can obtain relief without encountering any serious social disapproval, it is unjust that sufferers whose lives are wrecked without hope of recovery should have no remedy. It may be argued that in many, if not all, cases, the insane person will have done nothing for which he can be blamed. This must be admitted, but, on the other hand, as suggested above, divorce might well be confined to cases where it inflicted no penalty.

THE second report of the Welsh Consultative Council, which appears this week, recommends the establishment of a Welsh National Council of Health to provide for the development and organisation of health services and institutions in the Principality.

THE Common Council of the City of London recently voted in favour of an increase of salary from £1500 to £2000 per annum for their medical officer of health, Dr. W. J. Howarth, C.B.E. It was, however, pointed out by the town clerk that the resolution had been carried by 84 votes to 64, and that under a standing order of the Corporation a two-thirds majority was necessary in such cases before the increase could be made. Dr. Howarth will, we hope with certainty, find the Common Council willing to renew its consideration of the matter at some future date; we are assuming the validity of the by-law, or the interpretation put upon it by the town clerk, as points which must have been duly considered.

INDEX TO "THE LANCET," VOL. I., 1921.

THE Index and Title-page to Vol. I., 1921, which was completed with the issue of June 25th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1 and 2, Bedford-street, Strand, W.C.2.

WATER-SUPPLY:

CONSIDERATIONS ARISING OUT OF THE DROUGHT.

(BY A SPECIAL CORRESPONDENT.)

OWING to the drought, the time seems opportune for dealing briefly with current events and opinions as regards water-supply. The war and its aftermath, and the experience gained during the drought, have taught us many lessons, and we are face to face to-day with an economic position of considerable gravity. It is easy to say "hands off" as regards water-supply and public health questions generally, but it is none the less true that poverty and misery are the forerunners of disease. Beyond question it is our bounden duty to apply fresh knowledge and new experiences to the problems of preventive medicine, and see if money cannot be saved without prejudice to health.

The severity of the drought, now partially broken, is common knowledge, but the following table usefully summarises a few of the salient meteorological features of the last six months:—

Camden-square, London. (British Rainfall Organisation.)

—	Mean temp. degrees F.		Rainfall in inches.		Duration of sunshine in hours.	
	1921.	Av. 1860–1919.	1921.	Av. 1881–1915.	1921.	1920.
February ..	40·7	39·9	0·18	1·67	46·8	32·7
March ..	46·8	42·2	1·19	1·83	113·8	107·3
April	49·5	48·0	1·29	1·54	191·7	73·1
May	57·0	54·5	1·03	1·76	227·6	186·8
June	61·8	60·2	0·37	2·02	221·7	180·2
July	69·4	63·4	0·13	2·38	253·9	130·7

Official Call for Information.

An interesting step has recently been taken by the Ministry of Health. Waterworks authorities throughout the country have been circularised, and certain particulars asked for. For example: (1) the average yield per 24 hours for the year 1920; (2) the minimum yield per 24 hours during 1920; (3) the minimum yield per 24 hours resulting from the present drought. As, in some instances, the flow will continue to decrease despite the advent of rain, measurements should be continued until the point of minimum flow has been satisfactorily established. There can be no question that the information obtained will greatly assist the future development of water-supplies throughout the country, as we have now a unique opportunity of gauging the yield of water under unprecedented conditions.

It may, however, be suggested that the present time is favourable for securing a large amount of other useful information. For example, it is extremely important to know how the *quality* of our water-supplies has stood the test of the prolonged drought and the remarkable meteorological conditions which have accompanied it, and how far the floods, which must follow, will affect the position. Sanitary and waterworks authorities and medical officers of health are, no doubt, alive to the fact that the present conditions of water-supply are, apart from questions of deficiency, intensely interesting from the point of view of *quality*, and that the advent of rain will not rob the subject of its importance. Indeed, in many instances, when the fear of scarcity has disappeared, questions of purity will immediately arise. For example, what kind of water is going to be impounded, in unprecedented amount, into heavily depleted reservoirs, and are all wells, the output of which has been in most cases steadily diminishing, going necessarily to yield, in due course, exactly the same quality of water as characterised the past?

It is to be hoped that the opportunity has been, is being, and will be seized to collect information of order to avoid the implication that any one form of treatment would be practised in it to the exclusion of others. In order to preserve the individuality of the institute as a personal memorial to King Edward, it was decided not to merge it in any Government organisation like the general hospital; the Government granted a convenient site and the subscriptions amounted approximately to Rs.2¼ lakhs. The Government also obtained sanction from the Secretary of State to contribute an equivalent sum for the establishment and maintenance of the institute.

Plans and estimates, showing an expenditure of Rs.80,000, were prepared and approved, and the foundation-stone was laid by Lord Pentland on July 16th, 1917. Owing to war conditions and the difficulties connected with labour and supply of materials, progress was slow, and the costs gradually increased until expenditure amounting to Rs.280,000 was incurred. Moreover, the securities belonging to the committee, of the face value of Rs.5.15 lakhs, depreciated 50 per cent., and only the generosity of the Madras Government prevented the closing down of the tuberculosis institute, which, in temporary quarters, has given relief for the past five years to about 3000 patients per annum.

The institute has now been formally opened by Lord Willingdon, the Governor, in the presence of a large medical and lay gathering. In an introductory statement Archbishop Aelen, chairman of the committee, described the history of the institute and outlined the objects for which it had been established under the following heads: (1) relief to the tuberculous sick; (2) training of medical practitioners, students, and nurses in a knowledge of the diagnosis, treatment, and management of tuberculous patients, and public health administration connected therewith; (3) research work connected with tuberculosis; and (4) dissemination to the public by lectures and leaflets of information and knowledge relating to the disease. The chairman also explained that a tuberculosis institute was only the first unit in anti-tuberculosis measures; the second unit, in the form of a block of tuberculosis wards, had been provided by the munificence of Rao Bahadur M. C. T. Muthia Chetti, who had contributed the sum of half a lakh of rupees for the purpose. He appealed to private benefactors to help in the provision of the other necessary units—viz., a sanatorium, a farm colony, and a hospital for advanced cases. The Governor, in declaring the institute open, stated that another stage had now been reached in the attack on tuberculosis. In Dr. Chandrasekhar the institute had for its head an able and experienced medical officer, under whose guidance its progress was assured. There had been apprehension regarding the opening of a temporary tuberculosis hospital in Temple Gardens, a building situated in the midst of a densely-populated area of the city; but this arrangement was merely temporary, the intention being to construct a block of tuberculosis wards in the close vicinity of the institute, and as soon as this block was complete the hospital in Temple Gardens would be closed. On the authority of those best qualified to know, he added, there was no possible risk of infection to those residing near Temple Gardens. He hoped that before many years were over a Presidency hospital with a medical college near by might make that locality the therapeutic centre of the city of Madras.

The institute, designed by the late Mr. Thomas, consulting architect to the Government, has two storeys, with a large central hall containing a broad staircase and roofed with a dome. On the ground floor are situated the waiting rooms for patients, the examination rooms, the treatment rooms, and dispensary; while on the upper floor are the laboratories and microscope rooms and the administrative offices. The floors and staircase are of polished marble, and in this institute Madras has a memorial to the late King-Emperor in every way worthy of the Senior Presidency of India.

Madras, July 7th.

CZECHO-SLOVAKIA.

(From our own Correspondent.)

The Ministry of Public Health and Physical Education is going to open at the Prague Medical Faculty post-graduate courses for physicians in the autumn. The course for general practitioners will include theoretical lectures as well as practical exercises in all branches of medicine. Another course, organised under the auspices of the Masaryk Antituberculosis League, will be for physicians desiring to become officers in tuberculosis dispensaries. The third course will be conducted along the lines of a venereal diseases institute. It will be open not only to physicians but also to teachers and other persons interested in the problem.

Tuberculosis Death-rate.

The tuberculosis death-rate in the Republic has shown a very sharp decline in the years following the war. The curve began to decline in the years 1885, when the rate stood at 460 per 100,000, and continued slightly to decline until 1900; after the latter year the downward trend of the curve became more rapid until the outbreak of war in 1914. At that time the rate was about 320; it rose rapidly to 380 in 1916, and reached a maximum figure in 1918, the year of the influenza epidemic. The figures for 1920 show that not only has the rate reached the pre-war level again, but that the general trend of the curve has been maintained; the rate for 1920 is 275, some 50 points lower than in 1914.

Popular Health Education.

The League of Red Cross Societies is carrying out a demonstration by means of a unit for popular health education. The unit, organised by Mr. Marshall C. Balfour, of the League, consists of a director, one advance agent, and two physicians as lecturers; an organiser will shortly be added. The unit has a truck equipped with a kinema apparatus of its own; lectures on tuberculosis, venereal disease, and child welfare are given to children in schools, to workers in factories, and to the people as a whole in public buildings. Pamphlets and posters on health topics are being distributed. The unit began its work in Prague, and is now touring the country districts. Its success shows that the unit system, as developed in France by Prof. S. M. Gunn of the Rockefeller Foundation, is applicable also to the conditions in Czecho-Slovakia. An international conference on venereal diseases will be held in Prague early next October; it is being organised by the League of Red Cross Societies, and will follow the same lines as the recent conference in Copenhagen. Delegates from Poland, Hungary, Roumania, Austria, Jugo-Slavia, and Greece will be invited to attend. This conference will not only give a new impulse to the fight against venereal diseases, but will also bring together, for the first time since the war, the representatives of these countries for a peaceful discussion of common problems.

Medical Library and the Rockefeller Foundation.

The city of Prague, which is at the present time the educational centre not only for Czecho-Slovak, but also for Jugo-Slav, Ukrainian, and Russian medical students, has not hitherto had a well-organised medical library or reading room. The Ministry of Public Health and Physical Education has recently opened on its own premises a library and reading room where some 120 periodicals, including German, French, and English publications, will be made accessible to every visitor. At the present rate of exchange it has been very difficult for even the universities to secure foreign publications; for this reason the Rockefeller Foundation has offered to supply these periodicals to the universities at the cost according to the pre-war rates of exchange, the Foundation itself meeting the difference due to the deterioration of the currency.

way injuring trade interests, destroying the amenities of the district, or endangering health. Indeed, by utilising a pure moorland water for augmenting the domestic supply of Sheffield, they were greatly contributing to the prosperity and welfare of that important city, and conserving the water and financial resources of the country, inasmuch as any alternative project for providing an equal quantity of potable water would have involved the ratepayers in a capital outlay of approximately £3,000,000, compared with £350,000. The proposed method of purification was by lime and soda treatment, followed by efficient filtration.

Parliament endorsed the wise proposals of Sheffield on all points of principle, but imposed certain reservations. The Report of the Select Committee on Local Legislation which considered the Sheffield Bill stated:—

"The Sheffield Corporation Bill contained entirely novel proposals with regard to water-supply. The Corporation were allowed, after full evidence being given, to substitute for compensation water, which they are now under statutory obligation to discharge into certain rivers, an effluent from their sewage works purified to a standard required by the Bill, and which standard is based to a considerable extent on the findings of a Royal Commission of some years ago. The urgent need for, and difficulty in obtaining, a further supply of water for domestic purposes, combined with the special circumstances affecting Sheffield, make this case suitable for testing an experiment, which, if as successful as the evidence suggested, would be of incalculable advantage in other cases, where suitable conditions exist for its application."

Compensation Water: Standard Rate of Consumption and Avoidance of Waste.

A striking instance of present-day tendencies to economy in water-supply is the challenge of the necessity for providing one-third of the supply as compensation water, irrespective of the real circumstances. This is a subject which must be thrashed out in the interests of the general community; it is not a matter to be governed solely by precedent.

The drought has taught us that sooner or later, but the sooner the better, some tangible conclusions should be reached as to what is a reasonable rate of consumption per head of the population. No doubt, the circumstances vary considerably in different places, but, excluding trade interests, some figure for domestic purposes should be arrived at which is economically satisfactory without departing from the needs of decency, good sanitation, or reasonable enjoyment. The standard, whatever it may be, should never be exceeded, unless the circumstances clearly indicate that there is no financial reason why a more generous supply should not be afforded. The manner in which people generally have recently economised in the use of water has been little short of amazing, but it is still more remarkable how much less water than has been actually employed is really necessary in the interests of health.

It is not contended that a householder should of necessity in the future elect to have a supplementary rainwater supply, use his "slop" water for garden manurial purposes, his "washing" water for the watering of plants, reduce his personal ablutions to a minimum, and never use clean water for flushing operations. Nevertheless, if the householder has no leaking taps and adopts altruistic principles in relation to public water-supplies, it is an incontestable fact that, without infringing on the calls of health, or suffering any sensible hardship, a considerable saving in water consumption can be secured. It needs to be remembered that a decreased consumption of water implies correction for increase of population, and therefore postpones fresh capital expenditure, or a rise in working expenses; alternatively, when a population is stationary it usually connotes an economic gain, or an additional security, for the reason that whatever purification processes are in vogue the working expenses are either reduced, or the plant can be worked to yield the most efficient results. Indeed, it might be urged on the highest plane of all that as decreased consumption means, or should mean, a purer water, every effort should be taken to secure economy in the use of water in order to safeguard the interests of health. These matters are of special importance in the case of double-pumping schemes, and in connexion with water-supplies which require carefully contrived methods of water purification.

The Cheapness of Water.

A pure and abundant water-supply is amazingly cheap, and our outlay on public health is a mere drop in the ocean of the calls made on our purse to-day; but the fact remains that however desperately we resent other and vastly more costly expenditure on other projects, our duty to the nation to economise *in all possible directions* remains unaltered. Equally frankly it should be emphasised that the proportion of the total cost of a water-supply which can be fairly attributed to purification processes is, in most cases, singularly small.

There appears to be no evidence that the health of the community has suffered in any way as a result of the prolonged drought.

FACTORY HYGIENE IN 1920.

REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS.

WE commented briefly last week on the medical aspects of the report[1] of Mr. R. E. Graves, H.M. Chief Inspector of Factories, printed in handy and convenient form similar to the publications of the Ministry of Health.

Danger in Industry.

The question of safety is dealt with by Mr. H. J. Wilson, who points out that two-thirds of all factory accidents are not due to machines, and that of the remaining one-third only a small percentage could be prevented by better guards. Education of the worker and personal care in avoiding risk are the means for preventing accidents. Safety committees, composed of workers, are the means to employ, and figures are stated which show how one such committee reduced an accident rate of 3·7 per cent. of total employees in 1916 to one of 0·8 in 1920; progress in this direction is said to be steady though slow. One point not referred to by Mr. Wilson appears to us of interest—viz., the comparatively low rate of accidents among women; in all industries 3·1 per cent. of males, but only 0·7 per cent. of females sustained accidents, while of these accidents 1·1 per cent. were fatal among males, and only 0·3 among females. Males are certainly exposed to greater risks in industry, but in the textile industries, where more women than men are employed and upon very similar work, we also find that 1·5 per cent. of males sustained accidents, and only 0·6 per cent. of females, while 1·3 per cent. of these accidents were fatal among males, and only 0·2 per cent. among females. Is it justifiable to conclude that women are "safer" animals than men, and more resistant when injured?

Mr. G. S. Taylor discusses the administration of the various codes of regulations governing safety and health in dangerous trades. Here special interest attaches to an investigation carried out by Mr. Macklin into the grinding of metals: the special danger is that from exposure to silica dust arising during the process from the old-time sandstone wheel. Now is reported the steady substitution for these grindstones of composition wheels fitted to semi-automatic machinery. Composition wheels wear away more slowly, and give rise to less dust, while the dust is less injurious as regards both size and nature, and is more easily collected and removed from the air by well-constructed exhaust ventilation. The substitution is reported to be taking place most rapidly in the cutlery trade at Sheffield with advantage to health and to finance, since the new wheels improve output; and Mr. J. Law considers that the complete elimination of sandstone will probably be reached in due course as experience determines the power, grit, grade, and bond required for the various types of grinding. The effect of this substitution is already of ophthalmia neonatorum, or more than 3 per cent. of the total births. Is this high percentage due to the large number of illegitimate births, or to the fact that every case of "slight discharge" notified by a midwife is counted as a notification? Fortunately, no permanent damage to eyesight resulted. The very marked shortage of houses is being greatly met by the Municipal Housing Scheme, which provides for the erection of 661 houses in three separate estates.

---

[1] Cmd. 1403. H.M. Stationery Office. Price 1s. 6d.

Ramsgate.

In his report for 1920, Dr. W. J. Bannister describes many of the well-known advantages of Ramsgate as a health resort. The estimated population for 1920 was 29,338. The birth-rate has gone up from 17 per 1000 in 1919 to 28 in 1920. The death-rates are, as Dr. Bannister suggests, no doubt affected by the influx of aged persons and invalids who come to reside in Ramsgate in the hope of prolonging their lives. Thus among the 339 deaths there are 45 from heart disease, 40 from cancer, and 27 from phthisis. Were it not for this, one would regard a general death-rate of 13·6 compared with 12·4 for England and Wales, and a tuberculosis death-rate of 1·22, slightly higher than that of Sheffield, as somewhat paradoxical. 1920 was a year of low infant mortality rates, and a rate of 71·6 cannot be considered satisfactory for a health resort like Ramsgate. The explanation is no doubt to be found in the large number of artificially fed infants. Thus we read, on page 39, the result of inquiries as to the feeding of infants born in 1919: "Of 451 of these children, 145 were breast-fed for 9 months; 72 were breast-fed for 6 months; 94 for 3 months; and in the case of 115 attempts at breast-feeding were made." Dr. Bannister has something to say about the unsatisfactory state of the law as regards adulterated milk. One would think that these health resorts in the South of England are in an ideal position to create a demand for grade A (certified) milk. We believe it is a fact that there is not at present a single grade A (certified) dairy farm in the "Garden of England." A centre for the treatment of venereal diseases was opened during the year. No houses were built during the year, and consequently the overcrowding due to some 200 houses being occupied by more than one family continues. 26 houses were demolished, mostly houses which had been damaged by air-raids or bombardments. Dr. Bannister also submits his report as school medical officer. Of 142 children suffering from "tonsils and adenoids," only 37 received operative treatment and many cases yielded to indirect treatment, such as the removal of carious teeth. Of 478 children of the 6 to 8 group examined at the schools by the school dentist, it was found necessary to refer 215 for treatment. Satisfactory arrangements have been made for the treatment of minor ailments at the school clinic and treatment was secured for a high proportion of the children referred for treatment on account of minor ailments, visual defects, and defects of nose and throat and teeth.

The Services.

ARMY DENTAL CORPS: AMENDED RATES OF PAY.

The rates of half-pay for officers of the Army Dental Corps, which were fixed in January last at half the rates of full pay, have been amended and will now be the rates provided for other arms of the Service in terms of Army Order 324 of 1919.

THE INDIAN MEDICAL SERVICE AND JAPAN.

An officer of the Indian Medical Service may be selected to proceed to Japan next year for three years' study of the language. It is remarkable that in India the officers of the Indian Medical Service share equally with the officers of the Indian Army all the opportunities and rewards for the study of foreign language, whereas in the British Army the opportunities offered to their combatant brethren are not shared by the Royal Army Medical Corps.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lieut. A. W. Gunn to be Surg. Lieut.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Temp. Maj. F. M. Rodgers relinquishes his commn. on ceasing to be employed at the Lord Derby War Hospital and retains the rank of Maj.

The undermentioned Capts. to be Majs.: (Bt. Maj.) G. H. Dive, (Temp. Maj.) L. C. Hayes, (Bt. Maj.) R. Gale, K. Comyn, (Bt. Maj.) F. R. Laing, (Temp. Maj.) A. S. Cane, J. M. Weddell, (Actg. Maj.) A. P. O'Connor, T. H. Dickson, H. G. Robertson, H. V. Stanley, P. C. Field, R. M. Davies, E. C. Stoney, and T. W. Stallybrass.

Lt. A. McD. Simson is secd. for service with the Egyptian Army.

ARMY DENTAL CORPS.

Capt. A. B. W. Rust to be Maj.

The undermentioned to be Lts., with the temp. rank of Capt.: Temp. Capt. N. H. Medhurst, from unemployed list, R.A.F. Dental Branch, and Flight Lt. J. H. W. Fitzgerald, Dental Surg., from R.A.F. Dental Branch.

SPECIAL RESERVE OF OFFICERS.

Lt.-Col. P. Paget to be temp. Lt.-Col., with pay and allowances as Maj.

TERRITORIAL FORCE.

Lt.-Col. A. E. Jerman relinquishes his commn. on account of ill-health and retains the rank of Lt.-Col., with permission to wear the prescribed uniform.

Capts. P. T. Tolputt and W. S. Richardson to be Majs.

Capt. J. Marshall (late R.A.M.C., Spec. Res.) to be Capt.

Capt. A. C. Pearson resigns his commn. and is granted the rank of Maj.

Capt. and Bt. Maj. C. S. P. Hamilton, R.A.M.C., vacates the appt. of Adjt., R.A.M.C. Schl. of Inst., Wessex Divn. (T.F.).

Capt. W. W. S. Sharpe, R.A.M.C., to be Adjt. of the R.A.M.C. Schl. of Inst., Wessex Divn. (T.F.).

Maj. H. W. Williams resigns his commn. and is granted the rank of Lt.-Col., with permission to wear the prescribed uniform.

Maj. G. P. Chappel resigns his commn. and retains the rank of Maj., with permission to wear the prescribed uniform.

Capt. G. F. Hardy (late R.A.M.C.) to be Capt.

Capts. W. A. Milne, H. A. Philpot, and G. C. Walker resign their commns. and retain the rank of Capt.

The undermentioned officers, having attained the age limit, are retired: Lt.-Col. J. M. Moir retains the rank of Lt.-Col., with permission to wear the prescribed uniform; Maj. W. G. Sutcliffe is granted the rank of Lt.-Col., with permission to wear the prescribed uniform.

Majs. A. Ehrmann, H. Dutch, and C. A. Morris retain the rank of Maj., with permission to wear the prescribed uniform.

Maj. H. Meggitt retains the rank of Maj.

Capt. T. S. Allan is granted the rank of Lt.-Col.

Capt. A. G. T. Hanks is granted the rank of Maj.

Capts. H. G. L. Allford, W. R. Murison, A. Ambrose, A. Macphail, J. F. Hall, J. K. Brownlees, and G. Eustace, retain the rank of Capt.

TERRITORIAL FORCE RESERVE.

3rd Lond. Gen. Hos.—Capt. W. S. Handley resigns his commn. and retains his rank.

DEFENCE FORCE.

Dep. Asst. Dir. of Med. Servs.—Temp. Lt.-Col. P. Paget to be Dep. Asst. Dir. of Med. Servs.

Asst. Dir. of Med. Servs.—Temp. Col. F. W. Higgs, Def. Force, relinquishes his temp. appt.

Temp. Maj. R. Davidson, Def. Force, to be Dep. Asst. Dir. of Med. Servs.

Lt.-Col. E. P. Connolly, R.A.M.C., to be temp. Col.

Capt. R. Davidson to be temp. Maj.

Temp. Cols. E. V. Gostling and F. W. Higgs relinquish their temp. commns.

The undermentioned relinquish their commns.: Temp. Majs. J. C. S. Burkitt and A. Robertson, Temp. Capts. W. Tresawna, J. C. Anderson (retains the rank of Capt.), R. M. Wilson, Temp. Lt. P. Lloyd-Williams.

2nd (Highland) Fd. Amb. (D.F.).—Temp. Capt. H. J. Rae and Temp. Lt. H. J. Dawson relinquish their commns. and retain their rank.

1st (Lond.) Fd. Amb. (D.F.).—Temp. Maj. E. Knight relinquishes his commn.

Temp. Maj. C. V. Bulstrode and Temp. Capts. H. Wilson and A. C. H. McCullagh relinquish their commns.

2nd (Northumbrian) Fd. Amb. (D.F.).—Temp. Lt.-Col. D. L. Fisher relinquishes his commn.

Temp. Capt. J. A. Stenhouse relinquishes his commn.

2nd (E. Ang.) Fd. Amb. (D.F.).—Temp. Capt. F. W. Poole to be temp. Maj.

3rd (S. Midland) Fd. Amb. (D.F.).—Temp. Lt.-Col. T. A. Green relinquishes his commn.

MEDICINE AND THE LAW.

THE DURATION OF PREGNANCY.

THE decision of the Lord Chancellor in the Gaskill case, which turned on the longest possible period of gestation, must have been anticipated by all who had followed the evidence. The husband, a soldier, had returned to duty 331 days before the birth of a large child, estimated to weigh about 11 lb. The Attorney-General was asked by the Lord Chancellor to call expert medical witnesses, and Prof. Henry Briggs, Dr. T. Watts Eden, and Dr. John Fairbairn gave evidence at the adjourned hearing. None of these witnesses was prepared to dogmatise on the impossibility of a 331 days' pregnancy, and the Lord Chancellor, having no other grounds for doubting the probity of the defendant, refused to grant a divorce. Various points of interest arose during the hearing, though the case was more of legal than of medical import. The only point of difference between the views of the expert witnesses was that Prof. Briggs, from his personal experience, maintained that the post-mature child did not invariably show increased size, weight, and general development, whereas Dr. Eden agreed with Dr. Fairbairn that he would not credit a 331 day duration of pregnancy in a hypothetical case unless the child showed decisive evidence of post-maturity. It is quite possible that some of the long cases in Prof. Briggs's own series—the longest of these lasted 306 days—may have arisen from a delay in conception, the spermatozoa remaining alive but ununited. The length of life of the ununited spermatozoa is a factor which remains unsettled, though recent German investigations suggest that it may extend up to 14 days.

Medical Precedents.

The problem set before the experts was not complicated. They were not asked to prove that pregnancy can last 331 days, but merely to state any scientific reason which would make such a duration physically impossible. The word "scientific," used so frequently by those conducting the case, was rather a bitter reminder of the difficulties attending controlled investigation in medicine, and especially in obstetrics. The medical witnesses had as the basis of their opinion only the records of other clinicians and their personal experiences, both dependent, not on trained observation under experimental conditions, but on the statements of more or less credible patients. In fact, our knowledge of the average duration of pregnancy and of its variations has been derived from reasoning which is purely deductive—from the application to a particular instance of a general law founded on experience rather than on experiment. Of what determines the onset of labour we remain ignorant. However, so constant and, within certain limits, so invariable is the period of gestation in any animal that it is almost a specific characteristic; the rarity of phenomena such as a 331 day pregnancy, reckoned from coitus, may be estimated from the fact that the longest previous record, in the series collected by von Winckel, is 315 days from coitus (336 days from the last menstrual period). In this case the child was abnormally large, weighing about 16 lb., whereas in the case under discussion no exact measurements of weight or size were taken. Surprise was expressed by the counsel for the plaintiff that the medical attendant of the defendant should not have taken special precautions to weigh the child in view of the extraordinary interest and momentous importance of a case in which his estimate of the probable date of labour, calculated from information received, was exceeded by so many weeks. The suggestion implies a degree of confidence between patients and doctors which need not, and too often does not, exist. Inaccuracy, misunderstanding, and occasionally domestic conditions may obscure the issue, and the practising doctor learns early in his career that it is impolitic to manifest too great an interest in discrepancies. However, periodical antenatal examinations are becoming more and more general, and may be expected to throw some light on these rare cases of prolonged gestation. For the record of the size of the uterus month by month gives confirmation of the dates supplied, and such records, if combined with those taken of the child after delivery, may serve in the future to differentiate cases in which the abnormal duration is due to delay in conception after coitus from cases where it is attributable to other causes. Had the defendant been a regular attendant at an antenatal centre, and given consent to the production of her case-sheet, she might have been spared the unpleasant necessity of having her virtue vindicated in open court.

The Legal Bearing.

The judgment of the Lord Chancellor in the Gaskill case did not lay down any new rule of law. It has long been established in the courts that the legitimacy of a child born in wedlock must be presumed until it is proved by evidence that sexual intercourse between the parties did not take place at any time, when by such intercourse the husband could, according to the laws of nature, be the father of the child. In the case before him Lord Birkenhead could find no evidence of adultery; only the abnormal length of the pregnancy had raised the issues. There was nothing else to point to the respondent having committed adultery, and she had denied having done so. "I can only find her guilty," said his lordship, "if I come to the conclusion that it is impossible, having regard to the present state of medical knowledge and belief, that the petitioner can be the father of the child. The expert evidence renders it manifest that there can be no such impossibility. In these circumstances I accept the evidence of the respondent, and find that she has not committed adultery." This is a finding of fact based upon medical evidence. The medical knowledge and belief of a future generation may confirm it or may not, but as a judgment of the Lord Chancellor dealing with scientific evidence upon a physiological question of obvious difficulty it will be treated with respect; unless there is good reason to dissent from it. In relation to divorce, and to questions of parentage as affecting succession to property, it is of considerable moment that a period of 331 days is to be looked upon as a not impossible period of gestation. The civil code of France and the Rhenish civil code appear to agree in placing the limit at 300 days, the common law of Prussia having recognised 302 days as possible. This presumably implies that a child might inherit property in the United Kingdom, and at the same time be denied an inheritance of property from the same source situated in France or Germany.

INDIA.

(FROM OUR OWN CORRESPONDENT.)

King Edward VII. Memorial Tuberculosis Institute.

AT a public meeting held in Madras on May 17th, 1910, a general committee was appointed to decide the most appropriate form of memorial to the late King-Emperor Edward VII. It was resolved that the memorial should take the form of a hospital for consumptive patients, with a sanatorium or sanatoriums in suitable localities in the Presidency; a general appeal for funds was issued, and attempts were made to secure suitable sites. After some difficulty in the latter connexion, a resolution of the committee was sent to the Government in November, 1912, to the effect that the hospital should take the form of a tuberculin dispensary in the city of Madras, and that the balance of the funds should be devoted to the construction of a sanatorium in a suitable locality. The Government agreed to the proposal, but suggested that the institution be called a tuberculosis institute instead of a tuberculin dispensary, in

This is contained in the Philosophical Transactions for 1874, pp. 501–5, where he mentions cases in which the operative heat radiation originated from the faces of the experimenters.

I am, Sir, yours faithfully,

Victoria-street, Westminster, August 9th, 1921

AN INSTRUMENT WHICH IS SET IN MOTION BY VISION.

To the Editor of THE LANCET.

SIR,—In reply to Dr. Ian D. Suttie's letter in your issue of August 6th, the desirability of further work is obvious. My researches so far have been voluntary and unendowed, but there is a limit to one's endurance, at least on the financial side. Even Dr. Suttie must take this factor into account when complaining that I have not worked out yet all the variations of the eye force in diseases, cataracts, &c. He probably has already realised that time given to research must be at the expense of any medical man who has a living to get in practice. The tone of the critical remarks of Dr. Suttie is in sharp contrast to the interested and modest observations by the leaders of science to whom I gave the demonstrations. My assistant and I were impressed of course by the natural power but penetrating acumen of these men upon the numerous occasions that the effects were demonstrated before them. I hold no academic qualifications in physics and none are attached to Dr. Suttie's letter, but perhaps this was only his modesty.

Referring to Fig. 2, I must suppose that Dr. Suttie has not yet had time to make merely a few thousand observations on a model of that type. If and when he has done so, he will find with pleasurable surprise that while applying all his will-power or psychic force, or whatever it is, the condenser will not move, provided his vision is withheld. As a general principle I may remind him of the unwisdom of invoking a force as little known and as complex as psychology to explain something demonstrably due to a variation in a known (electrostatic) state. The force is reflectable, though the slight loss of power at so many feet from the mirror had to be ignored in the reference I made (p. 223). His reference to cataracts as controls is surely a feeble suggestion, and I gave him the best illustration of a means of cutting off the force by closing of the eyes, referred to under the heading of controls.

Dr. Suttie thinks my experiments have allowed me to outrun the appropriate amount of reflection. This may be so, as I have only been pondering them for four years, and it is one week since my work has reached him by means of THE LANCET. He may have heard me at the Congress giving more than once an amiable reminder to the questioners that when current electricity had just been found out it was unreasonable to expect us to be already driving the trams and telephones and lights by its power. Dr. Suttie's closing remarks appear to group him amongst the earnest searchers after the truth. The qualifications for that position are the production of much hard work and the other sacrifices. After such efforts in our subject he may well take the matter further than I have, and then he will not be so troubled by anxieties as to what fraud or abuse it may suffer by charlatans or others, who are the equivalent of the weeds in every garden. These latter activities will thrive as long as human credulity continues to like entertainment at least as much as instruction.—I am, Sir, yours faithfully,

Beaumont-street, W., August 8th, 1921. C. RUSS.

THE FÆCES IN ALIMENTARY DISORDERS.

To the Editor of THE LANCET.

SIR,—It is evident that in my article on this subject in THE LANCET of July 2nd I have failed to make my meaning clear to Dr. Chalmers Watson. I expressed the view that, in routine examination of the fæces, a Gram-stained bacteriological film was of little help; if, however, definite organisms, such as typhoid, were suspected, it was another matter. In that case (I left my readers to assume) the appropriate bacteriological methods were to be undertaken as a matter of course. I would assure Dr. Watson that my statement in regard to the small value of a Gram-stained film is based on experience in which the coöperation of both clinician and bacteriologist has been intimate; but I welcome his insistence on the necessity for such coöperation.

I shall be glad to learn the sort of conclusions which Dr. Watson himself is able to draw from Gram-stained films. Undoubtedly in some cases there are what for clinical purposes may be called "stools of putrefaction," in others "stools of carbohydrate fermentation," each with their more or less typical bacterial flora; but these conditions can be recognised without recourse to bacteriological investigation. Sometimes these findings are linked up with some abnormal clinical condition, sometimes they are associated with apparently good health; although, even when, for example, a "stool of putrefaction" is associated with the symptoms of so-called "intestinal toxæmia," the pathology of the condition is not at all clear. Undoubtedly the recognition of these types of stool gives useful indications for treatment, especially in the matter of diet. But to assume, as some clinicians appear to do, that the preponderance of a Gram-positive or Gram-negative flora has any special significance in that connexion seems to me to be at present quite unwarranted.

I am, Sir, yours faithfully,
Liverpool, July 30th, 1921. ROBERT COOPE, M.D.

THE OBJECTIVE STUDY OF THE NEUROSES.

To the Editor of THE LANCET.

SIR,—I am afraid that Dr. F. L. Golla has pushed the bottom out of his receptacle of interesting material in the last column of the report of his third Croonian lecture in your issue of August 6th. A woman tidies up immediately before childbirth because the probable date of it has been fixed, and because she knows that her chests of drawers will be looked over by others when she is in bed. His asking a midwife whether this tidying habit was common counts just nothing as a confirmatory procedure; as well might a laboratory analyst ask his bottle-washer to decide whether such or such a result was right or no. Only when Dr. Golla writes, "We have here an instinct untainted by any possibility of mimicry, and since its existence is apparently unknown, free from any complication due to suggestion," does he seem to invite controversy, for the remainder of the lecture is extremely interesting and useful.

What about most men and women tidying up before going to bed for operations of various kinds? Are they fetching up the old nest-making instinct?

I am, Sir, yours faithfully,
HAYDN BROWN.
Cavendish-square, W., August 5th, 1921.

LABOUR AFTER CRIMINAL ABORTION.

To the Editor of THE LANCET.

SIR,—The following notes of a case may interest gynæcologists and also medical jurists. Some years ago a married woman, finding herself two months pregnant, endeavoured to procure abortion by taking pills. These failing, she went one morning and, presumably, visited an abortionist; later in the day she joined her husband, who was innocent of what was going on, and spent the afternoon shopping with him. It was not until late that evening that she was seized with pain, after giving herself a douche. The following day a doctor was sent for, who found her suffering from commencing peritonitis. The next day, 48 hours after the symptoms began, she was operated upon, when there was no sign of any wound in the vagina or cervix, but there was general peritonitis with pus in the pelvis. A perforating wound, large enough to

Public Health Services.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Norwich.

Dr. H. C. Pattin gives the estimated population for 1920 as 125,700. The birth-rate has jumped from 16·35 in 1919 to 25·6 in 1920. The recorded death-rate —12·47—becomes 11·5 when corrected for the age and sex-constitution of the population. The infant mortality rate was 74 per 1000 births, 71 among legitimate infants and 133, or nearly double, among illegitimate infants. Dr. Pattin looks forward to the provision of better central accommodation for infant clinics and to the establishment of a model maternity hospital on the outskirts of the city. Over 1200 new babies were brought to the clinic during the year. The health visitors also act as school nurses; 2724 newly-born infants were visited and of these 475, or about 1 in 6, were reported to be ailing at the time of the first visit. Of the mothers, 2390 were reported to be healthy, 240 delicate, and 91 badly nourished; 730 infants were, for varying periods, fed with dried milk. "The results of the feeding with dried milk, on the whole, have been satisfactory—in some instances quite remarkably so." The standard income adopted for the purpose of supplying milk below cost price was 10*s.* per week per head in the family and Dr. Pattin believes that "this has worked out very fairly." Out of 2057 defects found among the school children 82 per cent. were remedied. Of the newly-notified consumptives 42 per cent. had a separate bedroom, 12 per cent. a separate bed in a double-bedded room, and 46 per cent. shared a bed. The joint scheme for treating and training consumptives of Norwich, Yarmouth, and the county at Stanninghall is making progress. Dr. Pattin does not think the attendance at the V.D. clinic is satisfactory and judges from the increase in ophthalmia neonatorum notifications that there has been some increase in the prevalence of venereal diseases; 120 new cases of gonorrhœa and 75 cases of syphilis attended the clinic from Norwich. There were 31 cases of ophthalmia neonatorum notified and one of these ended in complete blindness; the others recovered. As regards prevention of these diseases Dr. Pattin pins his faith to instruction and training of the faculty of self-control in the new generation and thinks that as regards the existing generation the practical limitation of effort to instruction concerning danger, moral suasion, and provision of treatment is not satisfactory. "The scarcity of houses persists, 48 only having been erected in 1920. The council's scheme provides for the erection of a total number of 1200; and that figure will hardly keep pace with the natural increase in population, leaving the real shortage pretty much as it is. The occupation of numbers of unsatisfactory dwellings has therefore still to be tolerated; and with this yet more unsatisfactory conditions of relative overcrowding."

The death-rate from pulmonary tuberculosis was 1·0 and from all forms of tubercle 1·3. The boot-making industry contributed 12·0 per cent. of the phthisical cases notified in the year and 20 per cent. of the deaths. As regard the prevention of tuberculosis Dr. Pattin says: "I attach more importance to the provision of adequate food than to any other measure." Many will agree with him especially if he refers to quality rather then quantity. We note that 149 smoke observations were taken and several persons cautioned. We shall not get much further with the purification of the air until local authorities realise that industrial smoke from boiler furnaces is quite unnecessary and take more drastic action against offenders.

Stoke Newington.

Dr. H. R. Kenwood's report for 1920 gives the estimated population as 52,084. The birth-rate was 23·1, against 16·8 for the preceding year, and the recorded general death-rate was 12·4, which is above that of 14 other metropolitan boroughs. The comparatively poor position of Stoke Newington among the metropolitan boroughs, Dr. Kenwood explains, is due to an exceptionally heavy incidence of whooping-cough, scarlet fever, and diphtheria. The infant mortality rate was 80·1 and the death-rate from pulmonary tuberculosis 0·7, compared with 1·0 for London. "The borough of Stoke Newington is mainly a residential area, a considerable proportion of the population being employed elsewhere. The residences comprise those of the well-to-do and the tenements of the low-wage earner." At times during the year only the more urgent cases of scarlet fever and diphtheria could be removed, owing to lack of accommodation in the Metropolitan Asylums Board hospitals. The Ministry of Health have made suggestions for improving the service given by the joint Hackney and Stoke Newington tuberculosis dispensary by the provision of an evening session, a special schools session, and an arrangement by which the time during which patients are kept waiting will be reduced to a minimum.

The work of the antenatal clinic grows. Dr. Kenwood thinks that when the midwife is more fully trained "she will become the ideal antenatal health visitor." He also voices the need for dental treatment and suggests a joint dental clinic with the education authority. The day nursery costs the borough over £400 a year and there were only 5000 attendances in 1920. We are not surprised that the committee are to consider closing it. Stoke Newington, like other towns, is suffering from overcrowding, a shortage of houses, and a difficulty in getting war arrears of repairs cleared off. Dr. Kenwood has a good deal to say, too, with regard to careless and destructive tenants, and thinks we need additional powers to punish them as a help towards their education.

Blackpool.

The estimated population of Blackpool is 70,515 and during recent years the town has had more deaths than births. Dr. E. W. Rees-Jones, in his report for 1920, submits a table showing that the birth-rate in 1878 was 38·8 per 1000, that in 1913 it was 16·25, in 1918 10·63, in 1919 11·84, and in 1920 it has risen to 16·71.

Dr. Rees-Jones tells us that the chief occupation of the inhabitants is catering for visitors, but that there is a strong tendency to establish industries, such as the manufacture of waterproof coating, which employ female labour. The industries of the town are healthy. With regard to the low birth-rate, Dr. Rees-Jones points out that there is a low proportion of married women below the age of 45 years. The percentage of illegitimate to total births has always been high in Blackpool. Thus the figures for the eight years beginning with 1913 have been as follows: 8·05, 6·87, 7·62, 8·81, 11·52, 11·18, 11·98, and 8·31. In spite of the large number of illegitimate births, the infant mortality rate was 69·6, but Dr. Rees-Jones says, "We must aim at a rate not exceeding 50." Of the 82 infant deaths, 13 were those of illegitimate infants, and 57, no less than 70 per cent. of the total, died before reaching the age of 3 months. The death-rate (corrected for age and sex constitution of the population) during 1920 was 13·63. The death-rate from phthisis (Dr. Rees-Jones apparently does not give the rate from all forms of tuberculosis) went up during the war and has now declined. The figures, beginning with 1912, are as follows: 0·79, 0·76, 1·07, 1·09, 1·06, 1·03, 1·31, 0·69, and 0·86. Dr. Rees-Jones recommends the corporation to provide dental treatment for tuberculous patients. Dr. B. F. Bartlett, assistant medical officer of health, has carried out the duties of venereal diseases officer and reports: "During the past 21 months the number of cases attending the clinic for treatment has increased ten times. The town being so largely a health and pleasure resort, with a fluctuating population, many cases are necessarily recorded as transfer cases without having completed their full course of treatment." More accommodation for the clinic is needed. There were 37 cases

ARTHUR BOWEN RICHARDS MYERS, M.R.C.S., L.S.A.,

LATE BRIGADE-SURGEON, BRIGADE OF GUARDS.

Colonel A. B. R. Myers, who as army surgeon in the late "sixties" did much work in connexion with disorders of the heart in their relation to the soldier's life, died at his residence, St. George's-road, London, on August 6th, within a few days of the eighty-third anniversary of his birth. Born in 1838 at Tenby, he was educated at St. David's and qualified M.R.C.S. and L.S.A. in 1859. After having acted as prosector to the Royal College of Surgeons of England, he joined the Coldstream Guards as assistant surgeon, and between this time and that of his appointment as surgeon-major in 1883 did most of the cardiac work with which his name is associated. He published in our columns an article on aortic aneurysm, in which he discussed the probable cause of its prevalence in soldiers as compared with sailors and with the male civilian population. He became convinced that the amount of aortic aneurysm in the army might be much diminished by the tunic being fitted more loosely round the neck and upper portion of the chest. "I cannot see," he wrote, "the propriety of making any portion of the soldier's dress so tight as to place him at a great disadvantage in regard to health, comfort, and usefulness, when actively employed, and especially now that the capabilities of each individual are being so much more studied than formerly."

In the following year he obtained the gold medal for his Alexander prize essay on the Ætiology and Prevalence of Diseases of the Heart among Soldiers. He also contributed the article on Exercises to Quain's Dictionary of Medicine, and papers on the heart and on syphilis to the Transactions of various medical societies. Whether or no Myers's theories were based on sound pathology—we have advanced far since then in our diagnostic equipment—his deductions were both wise and fruitful in results for the soldier's health and comfort.

Myers served in the Sudan Expedition of 1885 and was awarded the Suakim medal with clasp; he was promoted brigade-surgeon in 1888, and retired in 1891 with the rank of Brigade-Surgeon Lieutenant-Colonel. In later life he actively associated himself with municipal and church affairs. He was for many years a manager of the metropolitan Asylums Board; he served on the St. George's (Hanover-square) Board of Guardians, presided over a regional committee of the Charity Organisation Society, and sat on the Central (Unemployed) Body for London. This was indeed a useful life.

EDGAR FREEMAN MORRIS, M.R.C.S., L.S.A.

THROUGH the death of Mr. Edgar Freeman Morris at Hereford on July 31st from cerebral hæmorrhage the medical profession of Herefordshire is made the poorer by the loss of an able and conscientious surgeon and an honourable and straightforward colleague. He was a native of Hereford, where he was born in the year 1857. On leaving the Hereford Cathedral school he began his medical studies at University College Hospital, qualifying in 1880 as M.R.C.S. and L.S.A. Shortly afterwards he was associated in practice with his father in Hereford, and was elected a Poor-law medical officer. He joined the staff of the Herefordshire Infirmary in 1892, and at the date of his death was senior honorary consulting surgeon of that institution. He was a pioneer in the county of electrical treatment, and achieved a considerable success in the practice of this branch of medicine. A Conservative in politics and a staunch churchman, acting as vicar's warden over many years, he did not take a very active part in local municipal affairs, though he was a regular attendant on the city bench of magistrates. He was a P.M. of the Vaga Lodge of Freemasons and held provincial rank. He was chairman of the local medical war committee during the war and acted as consulting surgeon to three Red Cross hospitals. He was married twice and is survived by his widow, one son, and two daughters.

Medical News.

UNIVERSITY OF LONDON.—The following have been appointed to act as examiners for the Second Examination for Medical Degrees, Part II., in the Session 1921–22 (chairmen asterisked):—*Anatomy:* *Prof. W. Wright (Lond. Hosp. Med. Coll.) and Prof. E. Barclay-Smith (King's Coll.) together with the External Examiners (Prof. G. Elliot Smith and Dr. W. L. H. Duckworth). *Physiology:* Prof. F. A. Bainbridge (St. Bart.'s Hosp. Med. Sch.) and Prof. H. E. Roaf (Lond. Hosp. Med. Coll.) together with the External Examiners (Prof. J. S. Macdonald and *Prof. M. S. Pembrey). *Pharmacology:* Dr. P. Hamill (St. Bart.'s Hosp. Med. Sch.) and Dr. V. J. Woolley (St. Thomas's Hosp. Med. Sch.) together with the External Examiners (*Prof. F. Ransom and Prof. J. A. Gunn).

Mr. H. J. Waring has been elected chairman of the Brown Animal Sanatory Institution Committee. The Rogers Prize of £100 for 1921 has been awarded to Mr. Lambert Rogers for an essay entitled "The Surgical Treatment of Hyperthyroidism." Applications are invited for the William Julius Mickle Fellowship, of the value of at least £200, which is awarded annually by the Senate to the man or woman who, being resident in London and a graduate of the University, has in the opinion of the Senate done most to advance medical art or science within the preceding five years, and has therein shown conspicuous merit. Applications must reach the Principal Officer of the University not later than the first post on Oct. 1st, 1921. The Senate invite applications for the following readerships:—Readership in Psychology, tenable at King's College (salary £500 a year: latest date of application, Sept. 16th, 1921); Readership in Pathological Chemistry, tenable at University College Hospital Medical School (salary £700 a year: latest date of application, Sept. 15th, 1921). Further particulars may be obtained from the Academic Registrar, University of London, South Kensington, S.W. 7.

The following prizes and certificates were recently presented to successful students of the London Hospital Medical College by Mr. W. M. Pryor, Chairman of the College Board:—

"Price" Entrance Scholarship in Science, £100, R. W. Thomas; "Price" University Scholarship in Anatomy and Physiology, £52 10*s.*, W. R. Brain. Entrance Science Scholarship, £50, W. A. Taylor. Duckworth Nelson Prize in Practical Medicine and Surgery, £10, L. R. Fifield and G. H. E. H. J. Jones (equal, prize divided). Sutton Prize in Pathology, £20, D. S. Russell. Anderson Prizes in Elementary Clinical Medicine, £5, (1) K. E. Tresilian and J. L. Cox, (2) D. Waterfield and W. R. Brain (equal, prizes divided); honorary certificates, N. Gray Hill, F. C. Hunt, L. O. Lindsay, E. G. Snaith, E. W. Morris, M. C. N. Hadley, K. W. Todd and R. M. Morris. Arnold Thompson Prize in Diseases of Children, £15, J. V. Good; honorary certificates, D. J. Cox and D. S. Russell. Buxton Prize in Anatomy and Physiology, £31 10*s.*, H. W. Taylor and K. W. Heritage (equal, prize divided); honorary certificates, F. B. Byrom and D. Frost. Letheby Prizes, (1) Organic Chemistry, £15, W. A. Taylor; honorary certificates, R. W. Thomas, C. P. Donnison, J. T. Fathi and E. C. Hudson; (2) Chemical Pathology, £10, R. T. Brain. *Clinical Medicine*, £20 Prize, G. H. E. H. J. Jones; honorary certificates, M. E. Kennedy, L. R. Fifield and D. J. Fox. *Clinical Surgery*, £20 Prize, G. H. E. H. J. Jones; honorary certificate, L. R. Fifield. *Clinical Obstetrics and Gynæcology*, £20 Prize, D. S. Russell and C. S. Cloake (equal, prize divided); honorary certificate H. R. Ashton. *Elementary Clinical Surgery*, £5 Prizes, (1) L. R. Fifield, (2) A. Barker, (3) W. R. Brain and (4) S. A. Grant; honorary certificates, F. H. Mather, C. R. McClure and R. M. Morris. *Minor Surgery*, £5 Prizes, (1) M. F. B. Lynch, (2) G. King; honorary certificates, E. C. Hudson and D. J. Martin. *Practical Anatomy*, £5 Prizes, (1) F. Byrom, (2) F. C. Nicklin.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At the recent election of officers by the President and Council, Sir Humphry Rolleston and Dr. Horace G. Turney were appointed to take the place of Dr. Hector Mackenzie and Sir John Rose Bradford as Censors; Dr. G. F. Still to take the place of Dr. A. F. Voelcker on the Library Committee; Dr. W. Aldren Turner, Dr. H. Morley Fletcher, Dr. A. P. Beddard, and Dr. Charles Bolton to fill vacancies as Examiners in Medicine; Dr. J. P. Hedley, Dr. T. G. Stevens, and Dr. J. D. Barris to fill vacancies as Examiners in Midwifery. Dr. C. R. Box and Dr. Hugh Thursfield were appointed Examiners for the Murchison Scholarship.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Final Examination held from July 5th to 25th the following candidates were approved in the undermentioned subjects, but are not eligible for diplomas:—

Medicine.—Edith I. L. Abbott, Univ. Coll.; M. T. Ahmed, Guy's; N. A. Aiengar, Bombay and Guy's; O. A. Akjalg, Liverpool; Charlotte K. J. Almond, King's Coll.; S.

Correspondence.

"Audi alteram partem."

THE VOLUNTARY HOSPITAL SYSTEM.

To the Editor of THE LANCET.

SIR,—Your leading article in THE LANCET of July 30th (p. 237) is, if I may say so, both opportune and apposite. It is essential that those who support and those who criticise the "voluntary hospital system" should, as you say, agree as to "what it is of which they are speaking and thinking"; otherwise we may find that we may be agreed where we are *not precise and* precise where we are not agreed. No doubt, as Pascal said, it is desirable to define all our terms and prove all our propositions; nevertheless, as John Hunter remarked, definitions are of all things the most damnable.

When King Edward's Hospital Fund, towards the end of last year, set itself to consider what principles of policy should be put forward with a view to preserving the voluntary system, I submitted a memorandum on the subject, in which I said:—

> "It is well to have some definite notion of what is implied by the '*voluntary hospital system*.' The voluntary hospital system, as it has been generally understood in this country, usually implied: (1) That the hospital is *mainly* supported by voluntary subscriptions or endowments; (2) that the staff consists of honorary physicians and surgeons who render *voluntary and gratuitous* service to the patients; (3) that eligible patients are freely admitted, and any contributions towards expenses they can make are *voluntary offerings*; (4) that the hospital is managed by an unpaid voluntary board, elected by subscribers, and *independent of any State or municipal department or* bureaucratic control."

I then went on to point out how the voluntary system had been menaced from without and from within, and undermined in regard to all these implications. The real problem appears to be whether this undermining is to proceed further, whether the process can or should be reversed, or whether equilibrium is possible and can be preserved in the position which at present obtains.

In a paper I contributed in 1912 to the Conference of the British Hospitals Association at Birmingham, entitled "Hospitals and the State," I observed that in this as in other matters communism was replacing voluntaryism, and that—

> "We have arrived at this stage, half unconsciously, as the result of a series of legislative enactments, nearly all making in one direction, but as is our wont in this country without any very clear preconception of the end in view, and often accompanied by ingenuous disavowals of any socialistic trend on the part of the authors of the legislation in question."

I am afraid that some ardent supporters of the "voluntary system" have, no doubt unwittingly, contributed in some measure to undermining it. Lord Cave's Committee cautiously avoided defining what the voluntary system is which they are convinced is "worth saving," and of which they say "it would be lamentable if by our apathy or folly it were suffered to fall into ruin." The Report, however, adumbrates certain policies which the Committee regard as hostile to, or incompatible with, "the voluntary system." Thus they insist "if the voluntary system is worth saving, any proposals for continuous rate or State aid should be rejected," although they add "we think it is clear that in order to save the hospitals from immediate disaster some assistance must be forthwith given from public funds." Again, they regard voluntary contributions by patients as "more in accordance with the voluntary principle" than requiring a fixed charge as a condition of admission. And again in reference to staff funds, to which in your article you direct special attention, the Committee think that any extension of the practice of carrying a percentage of grants from public authorities, beyond the present limits, to the medical staff would "endanger the future of the voluntary system." The bearing of the partial replacement of an honorary visiting staff by a *whole-time paid staff, subsidised from public funds*, on the preservation of the voluntary system does not appear to have engaged the attention of the Committee.

The newly constituted Voluntary Hospitals Commission have, however, ventured where Lord Cave's Committee feared to tread, and have vouchsafed the definition of a voluntary hospital:—

> "An institution (other than an out-patient dispensary) managed by a responsible committee, and wholly or mainly supported from voluntary sources (including income derived from endowments or investments), the object of which is to provide medical or surgical treatment of a curative character."

It remains to be seen whether this definition will hold, in the light of the discussions at Newcastle and elsewhere, and some may regret with you the difficulty of maintaining unmodified the voluntary system "in which most of us have been brought up, with all its splendid ideals and occasional defaults."

I am, Sir, yours faithfully,

W. J. COLLINS.

Regent's Park, N.W., August 2nd, 1921.

THE ULTRA-MICROSCOPIC VIRUSES.

To the Editor of THE LANCET.

SIR,—In a letter published in THE LANCET of July 23rd Dr. F. W. Twort draws attention to the work of d'Herelle and his own earlier work along similar lines. If the phenomena discussed are indeed due to ultra-microscopic viruses the credit of first describing them undoubtedly rests with Twort. I wish, however, to reiterate the opinion which was expressed in a paper recently published in THE LANCET[1] that these phenomena of interference with bacterial growth are more accurately ascribed *to the production by bacteria of relatively thermostable* substances, possibly of the nature of ferments. If this view is correct, and to some such explanation Twort appears, in his paper, to lean, then the credit of first directing attention to the phenomenon undoubtedly goes to C. Eijkmann, who did much careful work on the subject, publishing a number of papers between the years 1901 and 1907. Eijkmann has not given any definite name to the substances, and the name "autotoxin" suggested by Conradi and Kurpjuweit is inaccurate in so far as the substances produced often affect other bacteria more powerfully than those producing them. On the analogy, therefore, of leucocidins we have proposed that these substances should be called "bactericidins."

I am, Sir, yours faithfully,

JAMES WALTER MCLEOD.

University of Leeds, July 29th, 1921.

THE SUPPOSED EXTERNAL EFFECTS OF HUMAN VISION.

To the Editor of THE LANCET.

SIR,—In his interesting paper, Dr. C. Russ states that the only reference in literature to the subject with which he is acquainted is a paper by Lord Kelvin in the Philosophical Transactions of the Royal Society On the Supposed New Force of M. J. Thore. Surely he means not Lord Kelvin, but Sir William Crookes, who wrote a paper under this heading in which he ascribed Mr. Thore's results to the effects of heat radiation.

Dr. Russ and others interested in the subject should, however, also study Sir William Crookes's several and voluminous papers on Attraction and Repulsion resulting from Radiation, published in the Royal Society's Philosophical Transactions from 1873 to 1879, and particularly Crookes's historical account of experiments by numerous physicists from 1792 to 1871 on the subject of repulsion by heat.

---

[1] McLeod and Govenlock: THE LANCET, 1921, i., 900.

The Rev. James Marchant, Director and Secretary of the National Council of Public Morals for Great and Greater Britain, has received the honour of K.B.E.

Mails for Tristan da Cunha for despatch by the s.s. *Quest*, R.Y.S., which is to convey Sir Ernest Shackleton and his party on their Antarctic Expedition, will be accepted in London up to August 23rd.

The Dentists Act.—The Royal Assent to the Dentists Act, 1921, has been given, but no registration under its provisions can be effected until the Dental Board has been constituted, which may not be until some months hence.

Middlesex Hospital Medical School.—The winter session will open on Tuesday, Oct. 4th, when the introductory address will be delivered by Mr. G. Gordon-Taylor, at 3 P.M., after which the prizes gained during the previous year will be distributed by Sir John Bland-Sutton. The annual dinner will be held at 7.30 on the same evening at the Trocadero, Mr. Comyns Berkeley presiding.

Edinburgh Post-graduate Courses, 1921.—Post-graduate courses in connexion with the University and Royal Colleges will be held this year from August 14th to Sept. 9th inclusive, and will comprise (1) a general medical course and (2) a general surgical course. The composite fee for each course will be ten guineas for the four weeks, or six guineas for either the first or second fortnight. The medical course will include lecture-demonstrations, and, where possible, practical instruction on medical anatomy, medical side-room work, examination of the blood, X ray and electrical therapy, morbid anatomy and post-mortems; clinical instruction in medicine, diseases of children, diseases of the skin, and infectious diseases; and special instruction in the methods of examination of the nervous, circulatory, respiratory, alimentary, and renal systems. The surgical course will include lecture-demonstrations on surgical anatomy, surgical pathology, and surgical X ray diagnosis; clinical instruction in surgery at the Royal Infirmary and Royal Hospital for Sick Children; clinical instruction in venereal diseases; surgical out-patients; surgical and gynæcological operations; and special instruction in abdominal and renal surgery and the surgery of the mamma. A series of special lectures, open to all graduates, will be delivered thrice weekly during the month, on subjects of general medical and surgical interest. Further particulars of the courses may be had on application to the Hon. Secretary, Post-graduate Courses in Medicine, University New Buildings, Edinburgh.

County of London Panel Committee.—The recently concluded course of post-graduate lecture demonstrations in general medicine at Charing Cross Hospital having proved a great success, the Panel Committee are encouraged to arrange further courses during the coming autumn. The subject to be dealt with will depend upon the choice expressed by the majority of those joining, and will be either general medicine, general surgery, or midwifery and gynæcology. If sufficient names are obtained two or more courses may be arranged. The fee for any course will be 3 guineas, payable in advance to the Secretary of the Panel Committee. Practitioners desirous of joining should notify the Secretary of the Panel Committee as soon as possible, and will assist if they will enter for more than one course, signifying the course for which they have most preference.

Charing Cross Hospital.—A course of ten lecture demonstrations in clinical pathology will be held in the Institute of Pathology, Charing Cross Hospital, during September, October, and November, 1921. Lecturers: Dr. W. M. C. Topley, director of the institute, and Mr. Cole, university lecturer in biochemistry, Cambridge University. Fee for the course, 3 guineas, payable in advance to the Secretary of the Panel Committee.

St. Thomas's Hospital.—A further course on venereal diseases will be held during September, October, and November, 1921. Colonel Harrison, D.S.O., will give the lectures and supervise the practical teaching. Fee for the course, 3 guineas, payable in advance to the Secretary of the Panel Committee.

South-Eastern and North-Eastern Fever Hospitals.—The Panel Committee have arranged with the Metropolitan Asylums Board, for two courses of clinical demonstrations on the Diagnosis of Fevers and Treatment of Diphtheria, to be held (1) at the South-Eastern Fever Hospital, Avonley-road, New Cross; (2) at the North-Eastern Fever Hospital, St. Ann's-road, South Tottenham, N. The courses will commence on or about September 29th, and will consist of six demonstrations with cases. Each class will consist of not more than 12 members. Practitioners desirous of joining should make early application; the fee for each course will be £1 12s., payable in advance to the Secretary of the Panel Committee.

United States Public Health Service.—The hospital programme of the United States Public Health Service is being rapidly developed; nine new hospitals, which will accommodate more than 3000 patients, will shortly be ready for use. Three of these, in Iowa, Montana, and Oregon, with space for about 500 patients, should be in operation within two months. The Colfax hotel, at Colfax, Iowa, a building with over 130 acres of grounds, is being fitted to receive 200 patients. The Army hospital at Fort William Henry Harrison, near Helena, Montana, will be opened with 100 general patients, but may later be greatly expanded. It is hoped to open the hospital at Dawson Springs, near Hopkinsville, Kentucky, with 500 tuberculosis patients within five months. The Hahnemann Hospital at Portland, Oregon, for 164 general patients by July 1st, and the Speedway Hospital, at Chicago, for 1000 general patients, have already been completed. Of three Army forts handed over by Congress to the Health Service, that at Fort Walla Walla will shelter 284 tuberculosis patients; Forts McKenzie (Wyoming) and Roots (Arkansas) are each planned to accommodate more than 600 cases of nervous and mental disease. A naval station at Gulfport, Mississippi, has just been taken over from the Navy, and will be utilised as a hospital or home either by the Public Health Service or by some other branch of the Government.

Leeds Workpeople's Hospital Fund.—In 1887 an arrangement was made between this association and the charitable institutions of the city whereby the latter abstained from approaching the wage earners for direct support to the charities, but relied upon the systematic collection by a committee of workpeople of weekly subscriptions from men, women, and children in receipt of wages. Until recently the amount subscribed was one penny per week from each man, and one halfpenny from each woman or child. During the last 12 months an appeal has been made to the workpeople to double their subscriptions; additional collections are now made in the various clubs and public houses of the city and in some of the elementary schools; ward competitions and the annual gala also bring in varying sums. The total income for the year covered by the annual report amounted to £39,739, a sum exceeding that subscribed in any previous year, showing an actual increase over the past year of £13,931. The Fund makes grants to the various medical charities of the city, the General Infirmary always receiving the largest amount, which this year reached the sum of £20,000. The Leeds Public Dispensary receives £3000; the Hospital for Women, £2500; the Maternity Hospital, £1000; the Jewish Hospital and District Nursing Home, £1000; and smaller institutions, £75 to £50. In addition to the provision of money for the medical charities the Fund has purchased, and now administers, three convalescent hospitals, one for men and two for women. The benefits of these homes are limited to the subscribers to the Fund, but admission to them is not regarded as a right of any subscriber, applications being carefully dealt with at a weekly meeting of the committee.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, August 15th.—12 noon, Dr. S. Pinchin: Diseases of the Heart. 2 P.M., Mr. MacDonald: Surgical Out-patients. Mr. Simmonds: Visit to Surgical Wards. 4.30 P.M., Dr. Paterson: Enlargements of the Abdomen.

Tuesday.—2 P.M., Dr. Burrell: Medical Out-patients. Mr. Banks Davis: Diseases of the Throat, Nose and Ear. 2.30 P.M., Mr. Addison: Visit to Surgical Wards. 4.30 P.M., Lecture:—Dr. Burnford: Clinical Medicine (I.).

Wednesday.—11 A.M., Mr. MacDonald: Demonstration of Cystoscopy. 2 P.M., Mr. Sinclair: Surgical Out-patients. Mr. Gibb: Eye Department. Mr. Addison: Operations. 4.30 P.M., Lecture:—Mr. Gibb: Ulceration of the Cornea (I.).

Thursday.—11.30 A.M., Obstetrical Registrar: Gynæcological Demonstration. 2 P.M., Mr. Simmonds: Orthopædic Department. Mr. D. Armour: Operations. 4.30 P.M., Lecture:—Mr. MacDonald: Enlarged Prostate.

Friday.—10 A.M., Mr. D. Buxton: Dental Department. 12.15 P.M., Dr. Burnford: Applied Pathology. 2 P.M., Dr. Pernet: Skin Department. 2.30 P.M., Dr. Pritchard: Visit to Medical Wards. 4.30 P.M., Lecture:—Mr. Simmonds: Surgical Emergencies (I.).

Saturday.—10 A.M., Dr. Burnford: Visit to Medical Wards. 12 noon., Mr. Sinclair: Surgical Diseases of the Abdomen.

Daily:—10 A.M., Visit of Post-Graduates to Wards. 2 P.M., In-Patient, Out-patient Clinics and Operations.

admit the tip of the little finger, was visible in the fundus of the uterus. The edges of the wound were sloughing. The patient's condition next day was apparently so hopeless that an attempt was made to obtain her dying deposition. She obstinately refused, however, to admit that any illegal operation had been done on her. With even greater obstinacy she refused to die, and after a long illness recovered.

She had been told that her illness must have destroyed any chance of her ever having children. About a year later she informed her doctor that she was again pregnant. Considering the damaged condition of her abdominal wall and the probability of adhesions, it seemed inevitable that labour would be difficult and that trouble might arise in the third stage of labour. Her confinement took place in due course, labour being easy and quick and the puerperium normal in every respect. To the obstetrician the case is an interesting illustration of the capacity of the uterus for recovery, and of the danger of foretelling a difficult confinement. To the medical jurist the case is important as the woman seems to have spent an afternoon shopping after perforation of the uterus with a weapon, however caused. In the law courts recently an eminent specialist stated in evidence that such a thing would be impossible, and, apparently, that definite expert pronouncement had an important bearing with the judge and jury. The case narrated above, therefore, also illustrates the danger of stating in a court of law that anything in medicine is impossible.

To any medical man interested in the case from the point of view of medical jurisprudence further details will be supplied.

I am, Sir, yours faithfully,
July 31st, 1921. X.X.X.

PRIVATE AND PANEL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—In the last paragraph under Public Health Services in your issue of August 6th, you state that "technically an insurance practitioner is entitled to charge a fee to the patient of another practitioner" who comes to the former for treatment in preference to his own "panel doctor," but you go on to say that "any practice of this sort would tend to be seriously prejudicial to the medical service for the insured." Why and how thus prejudicial? The panel doctor for whom the person has in the first case "signed on" for gets *his* capitation fee legitimately, though he does nothing for it, the second panel doctor gets his *fee* from the patient willing to pay it, and the insurance funds are saved the expense of medicine or anything ordered by the second doctor, for as the patient is a "private" one the second panel doctor either supplies it or sends his patient to a chemist with a prescription—presumably not to be supplied at the cost of the insurance finances. And the patient gets *his* satisfaction by consulting the medical man he wishes to consult. The patient can, of course, transfer to the practitioner he desires to attend him, but until he does so I do not understand how such a proceeding can be so terribly prejudicial to the medical service for the insured.

I am not and have never been on the panel list and I hope I shall never be compelled to put my name on it, but I am brought into contact daily with many panel practitioners and I am interested in questions concerning panel practice.

I am, Sir, yours faithfully,
August 6th, 1921. NON-PANEL.

AN APPEAL FROM THE RUSSIAN RED CROSS.

To the Editor of THE LANCET.

SIR,—As a Russian practising in this country permit me to associate myself with the stirring appeal made by my colleague, Dr. Belilovsky. I feel confident that the British medical profession, which has always been most responsive to any appeals in the name of humanity to alleviate suffering, will not turn a deaf ear to such a heart-rending S.O.S. from my unfortunate country. I view with great satisfaction that the International Red Cross Committee and the acting Director of the League of Red Cross Societies have jointly issued a statement proposing the formation of an international relief organisation to coördinate the activities of all the voluntary bodies. The Supreme Council, too, is giving attention to this urgent problem. But meanwhile what is needed is immediate assistance from each individual doctor in this country and from the British medical profession as a whole.

I am, Sir, yours faithfully,
L. ZEITLINE, M.R.C.S. Eng.
Gateshead, August 9th, 1921.

Obituary.

WILFRED W. E. FLETCHER, M.B.CAMB., D.P.H.,

LATE MEDICAL INSPECTOR, LOCAL GOVERNMENT BOARD.

IT was with great sorrow that the many friends of Wilfred William Ernest Fletcher heard of his death on July 31st, at the age of 64, in a London nursing home after a serious operation. In compliance with his expressed wish he was buried in the graveyard of his native village of Tarleton, which lies about eight miles from Ormskirk. Dr. Fletcher was a Lancashire man and came of an old clerical family well known in the county, his father having been for many years rector of Tarleton, and his late brother rector of Chorley and archdeacon of Blackburn. He was educated at Rossall School and Caius College, Cambridge, his medical studies being carried out at St. Bartholomew's Hospital. He took his B.A. degree in 1881 and his M.B. in 1884, in which year he obtained also the M.R.C.S. and L.S.A. Later he took the D.P.H. Not long after obtaining his medical qualifications Dr. Fletcher was appointed whole-time medical officer of health for the West Lancashire Rural District, and this post he held until 1892 when he was invited to join the medical department of the Local Government Board. This latter appointment he relinquished in 1917 after completing 25 years' service as a medical inspector. After his retirement the post of medical officer of health for the Metropolitan Borough of Hackney became suddenly vacant, and Dr. Fletcher was offered the temporary appointment until the end of the war, or until such time as a suitable permanent officer could be found. He filled this appointment for about two years and performed his duties to the entire satisfaction of the Council and of the staff which served under him. His genial personality was well known throughout a large part of England, especially in the Midlands and the North-Western Districts, in which he conducted many public inquiries, and numerous printed reports by him were published by the Local Government Board. It may be remembered that one of his more recent and interesting reports concerned a joint inquiry made by himself along with a superintending inspector of factories and a senior labour adviser of the Home Office, regarding the alleged danger of the transmission of certain diseases from person to person in weaving sheds by means of what is known among factory workers as "shuttle-kissing."

Fletcher was very popular with his colleagues at Whitehall, as also with the large number of medical men with whom he came in contact in the discharge of his official duties. His kindly disposition and engaging personality often turned opponents into friends. He held strong and pronounced views on politics, but his transparent honesty of purpose and his candour led those who differed from him to listen to his arguments even when expressed in somewhat forcible language. He leaves a widow to mourn his decease.

rates in respect of boys and girls between the ages of 16 and 18. The State does not make a weekly contribution to Health Insurance but provides two-ninths of the costs of benefit and the administration thereof. The State contribution to Unemployment Insurance is one-fourth of the contributions from employers and employed, that is, 3¾d. weekly in respect of men and 3¼d. weekly in respect of women.

Staff of Pensions Ministry Hospitals.

Mr. Hayward asked the Minister of Pensions what was the total number of patients and the total number of staff (including administrative, medical and nursing staff, and all other employees), respectively, employed at each of the following hospitals: Shepherd's Bush, Netley, Orpington, Ruskin Park, and Bellahouston.—Major Tryon supplied the following printed statement:—

	Staff.*	In-patients.	Out-patients.
Shepherd's Bush	412 (*a*)	543	511
Netley	109 (*b*)	191	90
Orpington	458 (*c*)	923	2
Ruskin Park	247 (*d*)	327	436
Bellahouston	344 (*e*)	717	1168

* Including part-time medical officers.

(*a*) Includes 265 domestic and lay assistants.
(*b*) ,, 61 ,, ,, ,,
(*c*) ,, 362 ,, ,, ,,
(*d*) ,, 136 ,, ,, ,,
(*e*) ,, 177 ,, ,, ,,

I may add that the proportion of staff to patients varies with the type of case treated in the hospital and with the structural arrangements of the hospital.

Friday, August 5th.

Criminal Law Amendment Bill.

The House considered the Criminal Law Amendment Bill on Report.

Mr. Macquisten moved a new clause providing that "any act of gross indecency between female persons shall be a misdemeanour and punishable in the same manner as any such act committed by male persons under Section 11 of the Criminal Law Amendment Act, 1885." This clause, he said, was one which was long overdue in the criminal code of the country. He had had professional experience of calamitous cases due to gross practices indulged in of this kind. These moral weaknesses dated back to the very origin of history, and when they grew and became prevalent in any nation or in any country it was the beginning of the nation's downfall. The falling away of feminine morality was to a large extent the cause of the destruction of the early Grecian civilisation, and still more the cause of the downfall of the Roman Empire. One could not go into the details; it was more a matter for medical science and for neurologists, but all lawyers who had had criminal and divorce practice knew that there was in modern social life an undercurrent of dreadful degradation unchecked and uninterfered with. He believed if the punishment of the law were imposed upon it it would go a long way to check and even to eradicate it. Neurologists would tell them how largely the spread of the use of cocaine and other drugs was due to the dreadful nerve deterioration which beset many of the idle part of the population. He had seen happy homes wrecked in this way. Only that night he had been speaking to a man, whom he had known for a comparatively short time, and who told him how his home had been ruined by the wiles of an abandoned woman who had pursued his wife, and later some other misconduct happened with a male person which enabled him to get a divorce. This was a matter with which it was necessary to deal on account of its civil and sociological effects.

Major Farquharson said that on behalf of those who were promoting the Bill he was very pleased to accept this new clause.

Colonel Wedgwood could not believe that the House would pass the clause, which would advertise a beastly subject. To call in the policeman to suppress a vice was the best way to encourage the knowledge of that vice and the spread of it. On the other hand it would lead to endless blackmail.

Sir E. Wild said that if hon. Members were to consult any neurologist, any great doctor who dealt with nerve diseases, they would be told that this was a very prevalent practice. He had the authority of one of the greatest nerve specialists for saying that no week passed that some unfortunate girl did not confess to him that she owed the breakdown of her nerves to the fact that she had been tampered with by a member of her own sex. He (Sir E. Wild) had consulted many asylum doctors and they assured him that the asylums were largely peopled by nymphomaniacs and people who indulged in this vice. He had also consulted the criminologists and they said that these practices took place. This vice did exist, and it sapped the fundamental institutions of society. It stopped childbirth, because it was a well-known fact that any woman who indulged in this vice would have nothing to do with the other sex. It debauched young girls and produced neurasthenia and insanity.

On a division the clause was read a second time and added to the Bill by 148 votes to 53.

Sir R. Newman moved to leave out the provision in Clause 1 (consent of young person to be no defence) to the effect that the party consenting should be guilty of a misdemeanour if he or she was of the age of 15 years. He urged that this provision would make it impossible to get a conviction, because it was really on the evidence of the child herself that in nine cases out of ten the case against the prisoner mainly depended.—Mr. Hohler seconded. On a division the amendment was negatived by 167 votes to 27.

Sir E. Wild moved to leave out Clause 2 (removal of defence of reasonable belief as to age of girl). With all the desire in the world to promote morality and protect young people against themselves it was not fair that this only defence a man had should be taken from him.—Major Hamilton seconded.

Mr. Shortt (Home Secretary) hoped the House would not accept the amendment.—Major Farquharson, speaking as a physician, appealed to the House to let the clause stand as a mere physical protection to the race.—On a division the amendment was negatived by 103 votes to 49.

The Report stage of the Bill was concluded. The motion for the third reading of the Bill was carried by 101 votes to 8.

Tuesday, August 9th.

Poison Antidotes Bill.

Brigadier-General Surtees introduced a Bill to provide that the receptacle of each poison sold by retail shall bear a printed description of an antidote for that poison. The Bill was read a first time.

Overcrowding at Dartmouth.

Mr. Rawlinson asked the Financial Secretary to the Admiralty whether the medical advisers of the Admiralty early in the year warned the Admiralty of the risks of overcrowding involved in the increased number of cadets at Dartmouth; whether the cadets were now sleeping in dormitories with less than 3 feet between bed and bed; whether some of the beds were directly under the windows and on more than one occasion the beds had been soaked with rain; whether the cubic space of air allowed per cadet was less than the space insisted on in industrial schools; and whether he would reduce the numbers at Dartmouth next term, either by sending more cadets to sea or otherwise.—Mr. Amery replied: As regards the first part of the question, I would refer to the replies on the subject already given to the hon. Member on March 23rd and April 5th respectively. The answer to the second part of the question is in the affirmative. As regards the third part, owing to the construction of the dormitories and the large amount of window space, it has been found necessary for a proportion of the beds to be placed to a greater or lesser degree directly under the windows, but the bottom halves of the windows can be easily closed in bad weather, leaving fanlights in the upper part open for ventilation, and, if necessary, the windows on one side of the building can be closed entirely. No reports have been made to the authorities at the College of any beds being wetted by rain. With regard to the fourth and fifth parts of the question, the amount of cubic space of air provided during the past term per cadet is more than double that insisted upon by the Home Office in the case of industrial schools, and under the arrangements already made the number of cadets at Dartmouth next term will be reduced to 540, as against 586 during the present term. This number will be further reduced in January next to about 495. I may add that, during the present term, there has been an almost complete absence of sickness amongst the cadets.

Coroners' Inquests in Ireland.—For some months past the holding of coroners' inquests has been prohibited in 24 counties and four county boroughs in Ireland. The absolute prohibition was revoked last week, and a fresh order was issued which permits coroners and juries to function "in any case in which the holding of an inquest may be authorised by the competent military authority." Our correspondent writes: It would have been wiser to maintain an absolute edict against the functioning of coroners, until the prohibition can be completely removed. The delegation of certain inquiries to a coroner and jury, and the choosing of others for military investigation, whether public or secret, is sure to arouse suspicion.

Solberg, *Leeds*; *D. D. C. Thomson, London*; Helen C. Tompson and Norah Walden, Royal Free; C. E. Whitting, Cambridge and St. Thomas's; and J. R. Wright, Manchester.

St. Thomas's Hospital Medical School.—Mr. R. A. Hill has been elected to an Entrance Arts Scholarship (1921, value £25), and Mr. J. M. Ashton has been elected to an Entrance Science Scholarship (1921, value £150).

Westminster Hospital: Annual Dinner.—The annual dinner for past and present students of Westminster Hospital will be held on Friday, Oct. 7th, at the Great Central Hotel. Sir Charles Ryall will occupy the chair.

Donations and Bequests.—Ancoats Hospital, Manchester, has received sums amounting to over £930, including £637, the proceeds of St. Jerome's Church (Ardwick) Bazaar, and £121, the proceeds of a swimming gala held by the Manchester Victoria Swimming and Life-Saving Society. The board of management of the Royal Infirmary, Manchester, in addition to a number of new annual subscriptions and increased annual subscriptions, acknowledge the receipt from various donors of £203.

Manchester: Precautions against Infantile Diarrhœa.—The Manchester Health Authority has issued a timely warning to parents of the dangers of infantile diarrhœa, particularly at this time of year and with the coming of rain after the long spell of hot weather. The local by-laws as to the removal of breeding places of the common fly in manure heaps are systematically and efficiently enforced; all stables are inspected, and arrangements made for the removal of refuse at least once a week, the incubation of flies being thus cut short. Householders are asked to assist in the work by burning all refuse and maintaining a high level of cleanliness on their premises. *It is advised that all food and milk be protected from contact with and contamination by flies or germ-breeding dust; that the soiled garments of infants be placed at once in a weak disinfectant solution of chloride of lime;* and that infants at the breast should, if possible, not be weaned during the hot months. The importance of securing immediate medical attention for a child attacked by diarrhœa is emphasised; if a private medical man is not available the child should be taken to one of the widely-scattered child-welfare centres. Steps have been taken to supply each householder with cards for notification, and the arrangements are so complete that public coöperation should secure effectual treatment of any outbreak which may occur.

Medico-Psychological Association of Great Britain and Ireland.—*The annual meeting of the Association was held on July 12th to 14th, at the home of the Royal* Society of Medicine and at the Springfield Mental Hospital, Tooting. The proceedings opened with the business meeting, under the presidency of Dr. W. F. Menzies, when a sincere tribute was paid to the lifelong work in the specialty of the recently deceased Sir George Savage; and a vote of condolence with the members of his family was passed by members rising in their places. The remaining sessions were presided over by Dr. C. Hubert Bond, the new President.

A large number of members were entertained at luncheon by Mr. A. H. Trevor (a legal member of the Board of Control) and the dinner was made memorable by the attendance of the Lord Chancellor, *the Minister of Health, and a really representative gathering of both professions.* Both Lord Birkenhead and Sir Alfred Mond assured the gathering of their sympathy with the aspirations of those concerned with the care of the mentally afflicted, and of their readiness to do their best to bring about the realisation of their aims. The retiring President and officers were cordially thanked. The new President's address was then delivered, and appears in this issue of The Lancet. Sir Robert Armstrong-Jones, in proposing a cordial vote of thanks to Dr. Bond for his address, referred to the great help given to psychological medicine during the war by Sir Alfred Keogh, and to the increasing attention being *given to borderline cases of* mental disorder. *Dr. J. G. Soutar seconded, and alluded to* the enthusiastic *work done for the Association by Dr. Bond when he was its general secretary.* The vote was carried by *acclamation.*

Among the subjects on which papers were contributed, practically all followed by long discussions, were:—Dr. P. W. Bedford: The Goldsol Test in Mental Disease. Dr. Edwin Goodall: Demonstration of X Ray Photography of Barium Meals in Cases of Dementia Præcox. Dr. E. Goodall and Dr. H. A. Scholberg: A Note on the Diastase-Contents of the *Urine in 120 Cases* of Mental Disorder. Dr. T. S. Good: *The Oxford Clinic (followed by a memorable speech by Prof.* Robertson, Edinburgh). *Dr. C. S. Myers*: Psychological Medicine in Relation to *Industry.* Dr. Edward Mapother and Dr. J. E. Martin: Recurrent Phantasies of Infancy and Childhood as a Source of Delusions. Dr. Wilfred Caroleu: Legislative Restrictions in Connexion with the Treatment of Incipient Insanity. Dr. G. A. Auden: Mental Defect and the School Medical Service. Dr. Henry Devine: Expatiation Mechanism in a Case of Schizophrenia. Dr. Bernard Hart: The Problem of Prevention in the War Psycho-neuroses. *Dr. W. Ford* Robertson: *Chronic Bacterial Infections in Dementia* Præcox. *Dr. T. Beaton*: *Change of Phase in the Psychoses. Dr. Henri Colin (Paris)*: Mental Hygiene and Prophylaxy. Dr. J. T. Dunstan: The Feeble-Minded Problem in South Africa. Prof. William Brown: Psychology and Psychotherapy. Friday was devoted to visits to various mental hospitals, and the meeting at the Springfield Hospital was followed by a garden party.

Notes, Short Comments, and Answers to Correspondents.

THE PROBLEM OF THE HEAD LOUSE.*

By G. A. Auden, M.D. Cantab., F.R.C.P. Lond., D.P.H.

The war has taught us much concerning the life-history and habits of the head louse, and moreover has shown that disinfestation is by no means the easy matter it was at one time supposed to be. This is true of both the head and body louse. It is with the former that I propose to deal in this paper.

With the absence of any proper conveniences, in an overcrowded home, amidst her multifarious duties, it is not altogether surprising that many a mother gives up in despair the attempt to keep her children's heads free from infestation. However, it is really quite uncommon nowadays to find a child who has not had some form of anti-louse treatment. This has been one of the difficulties in my investigation detailed below. It will be admitted that, in view of these difficulties, the discovery of an effective agent for the disinfestation of the head would be a great social service to the community.

Necessary Properties of Effective Agent.

Such an agent, to be of general value, must be (1) non-toxic, (2) non-irritant, (3) non-inflammable, (4) lethal or repellent to the louse, (5) have penetrating power sufficient to destroy the embryo, (6) soften and thus facilitate the removal of the nit. And lastly it must be cheap, readily accessible and easily applied, without any complicated ritual of procedure.

Prof. G. H. F. Nuttall[1] gives a very long list of insecticide substances which have been recommended by various observers. Only a comparatively small number of these, however, conform to the above conditions, while many must be ruled out of court for one reason or another. Again, many of the materials described can be used for clothing only, and require more prolonged application than is possible for treatment of the head.

Advantages of Derbac.

After trials of various substances, I have been experimenting with a soap sold under the proprietary name of Derbac, which appears to possess certain advantages of chemical and physical composition. Made primarily by the action of caustic soda upon the starch, proteins, &c., contained in cereals, the molecular composition is different from that of the ordinary fat soap, and the colloidal products produced in its manufacture are of a different character. In the first place it does not form an insoluble lime soap in combination with the calcium of the water, and there is a much less precipitation of the fatty acids in consequence. The result is that much more fatty acid remains in the solution. Certain soda-starch compounds are formed, and the soda acts upon the proteins to produce soaps of amino-acids and ammonia. Further, Derbac contains a heavy percentage of birch tar, which appears from Prof. Nuttall's list as a useful remedy, repellent to the louse and a well-tried remedy for skin affections. The tar is presumably emulsified in the course of the manufacture. It is probable also that as the birch tar contains cresols and other phenolic bodies, phenolates are produced. I am inclined to regard coal-tar derivates as undesirable for and irritating to the skin. This is seen in the action of carbolic acid on the skin, and in the well-recognised irritation of the skin caused by coal soot. Prof. Nuttall, writing of birch tar (p. 556), says, "Further tests should evidently be made."

"True Wetting" and Destruction of the Nit.

The chemistry of soaps and the colloidal conditions which are formed by their use are exceedingly complicated, and not altogether understood. The cleansing properties are probably in the main due to "true wetting" of the substance caused by an alteration of the surface-tension and the formation of an emulsion which has an affinity for dirt, grease, &c. Many liquids do not truly wet a surface, and there is no "molecular intimacy," as it is called. To be effective in destroying the louse and embryo, it would seem necessary that there should be this true wetting action, accelerated by the essential thorough lathering of the head.

The problem is that of the nit rather than of the louse. The latter can be dislodged by many repellent substances accompanied by mechanical means, such as the Secker comb, especially if it is enmeshed in a good lather. Lice, however, are so resistant that only a prolonged application of most substances, with the exception of the mineral oils, will kill them. Moreover, lice which appear to have been killed are frequently quite active a couple of hours later. Thorough combing out is therefore essential.

The destruction of the embryo in the nit is the chief object to be aimed at. The dislodgment of the dead nit is a secondary consideration. It is not generally recognised that the louse lays her eggs close to the scalp, and that the distance of the nit away from the root of the hair to which it is attached is a measure of the age of the nit. I believe that many a parent has been prosecuted and even fined for louse infestation, although the nits are old shells from which the louse has long hatched out.

Test of Disinfestation Material.

In order to test any disinfesting material, experiments must be carried out under certain predetermined conditions, with definite control experiments. These may be summarised as follows:—

1. Hairs must be taken from children who have received no previous treatment, and on whose heads there are living lice.
2. The hairs supporting nits must be taken immediately before and immediately after treatment with the disinfestor chosen, and incubated under identical conditions, at a temperature of 90° F., the optimum temperature for louse incubation.
3. Nits must contain embryos in both cases. For this purpose it is necessary to examine a number of hairs microscopically. In any given sample of hairs far more shells than living nits are found.
4. After incubation the nits taken before treatment should either hatch out or show evidence that the embryo has continued to develop, while the nits, after treatment, should show no evidence of continued development. Sometimes active pharyngeal movements in the contained embryo can be seen, thus affording definite evidence of its life.

It is thus difficult to carry out experiments which conform to these stringent conditions, or to hatch out lice under artificial conditions, and a good deal of experience is necessary to detect changes in the embryo indicative of death. Moreover, there is no means of learning what percentage of nits in an untreated case hatch out. Under natural conditions a certain proportion of nits probably do not produce living lice.

Results of Experiments.

In my experiments the hairs were placed in test-tubes in an electric thermostat incubator regulated to a temperature of 90° F., and the lice placed in small glass receptacles with a perforated false bottom of glass. In some cases a small plug of damp cotton-wool was placed at the bottom of the tube to prevent desiccation. This, however, appeared to be unnecessary, and increased the difficulty in looking for hatched-out lice.

The result of the 12 experiments may be summarised as follows:—

(*a*) *Adult lice.*—After the head had been well lathered for about ten minutes, the majority of the lice remained motionless, and could be picked or rubbed off with fair ease. When placed upon filter-paper and in a glass cell they appeared to be dead, but had again become active within two hours, in all cases making their way into the lower compartment. The notable fact, however, was that in the three experiments with live lice, all were found dead on the following day, after about 16 to 20 hours' incubation at 90° F. This is remarkable, for the louse is extraordinarily resistant to chemicals if the application is not prolonged. In a control experiment live untreated lice lived 60 hours in the incubator and presumably died of starvation. I have found lice to revive after a drop of chloroform has been placed upon them. (To the flea chloroform causes instantaneous death.) They also survived drops of a mixture of absolute alcohol and clove oil, of such strength as to cause intense burning sensation on the tongue or lip. It would appear, therefore, that the treatment, although not immediately fatal, does have a lethal effect upon the adult louse, and that two or three applications would be efficacious in freeing a head from lice by these means. A difficulty which is often found in these cases is the presence of impetiginous crusts under which the lice seek shelter. It is therefore a wise precaution to take steps to kill the lice which have been detached, by boiling the towels which have been used or by pouring boiling water upon them.

(*b*) *Nits.*—I prepared a considerable number of slides of nits incubated at 90° F., taken immediately before and after treatment. That some embryos survive a single treatment was proved by their hatching out, but the evidence of the microscope goes to prove that far more hatched out, as judged by the vacated shells, from the untreated hairs. In by far the majority of slides made from untreated hairs, the nits were found to be empty, and the bottom of the test-tube in which they had been incubated was littered with

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, AUGUST 2ND.

Milk for Tuberculous Persons.

Mr. THOMAS GRIFFITHS asked the Minister of Health whether he was aware that the Hertfordshire County Council proposed to provide milk for tuberculous persons and that the provision made would allow for a supply of milk for 47 persons in addition to the supply provided by the insurance committee for 153 insured persons; whether the limitation of the supply to persons with tubercle bacilli in the sputum excluded many persons, especially children, for whom milk was necessary; and whether, in view of the inadequacy of one pint of milk per day for the purpose, he would consider, in the interests of public health, withdrawing the regulation which limited the expenditure of local authorities, if they were to receive Government aid, to £2 per 1000 inhabitants.—Sir A. MOND replied: I understand that the scheme of the county council provides for the supply of milk to about 200 tuberculous persons at any one time and that this is the maximum provision which can be made within the limits of an expenditure of £2 per annum per 1000 inhabitants of the county. The limitation of the supply to persons with tubercle bacilli in the sputum does not apply to cases of non-pulmonary tuberculosis, the majority of which are children. The Exchequer grant allows on the average an expenditure of double that hitherto incurred by the insurance committees. I can hold out no hope of an increase in the amount of the grant.

WEDNESDAY, AUGUST 3RD.

Opium Cultivation in China.

Mr. STEWART asked the Under-Secretary of State for Foreign Affairs whether the Government could give any information as to the position of opium in China at the present time; whether the Chinese government undertook to put down the cultivation of opium in China when we gave up the export from India; whether it was the fact that great cultivation was being carried on in many Chinese provinces and that smuggling of native opium into Shanghai and Hong-Kong was taking place; and what the Government proposed to do to get China to carry out her treaty obligations.—Mr. HARMSWORTH replied: Papers are now being prepared for submission to Parliament showing the present position of opium cultivation in China. It is the case that China undertook to put down cultivation as the condition on which the export of opium from India was stopped. At that time opium-growing in China seemed to have been satisfactorily suppressed, but I regret to say that recent reports indicate a marked revival in certain provinces and there is evidence of smuggling of Chinese opium into Hong-Kong on a considerable scale. No doubt it is also smuggled into Shanghai. Strong protests have been repeatedly addressed to the Chinese Government, but have hitherto remained entirely unheeded. The hon. Member is doubtless aware that the League of Nations are now actively interesting themselves in the whole opium question.—Sir J. D. REES: Now that the real facts are known is it not time to consider a revision of our policy rather than run the risk of irritating China by trying to force her to carry out what she is obviously unable to carry out?—Mr. HARMSWORTH: I hope the policy will not be changed.

Necessity for Better Rural Housing.

Mr. LAMBERT asked the Minister of Health for what reason he was giving a precedence to large industrial areas over rural areas in the Government housing scheme, seeing that an increase of the rural population would ensure a greater supply of home-produced food being available for the inhabitants of Great Britain.—Sir A. MOND replied: It has been necessary to consider the relative claims of rural and industrial areas to the limited house provision at my disposal, and I think it will be generally recognised that more overcrowding prevails and that other health conditions are more unfavourable in large industrial areas than in rural areas, and while I am aware that there is a deficiency of houses in rural areas I have had under the circumstances to decide to give precedence to industrial areas.

Tuberculosis Hospital at Boston.

Mr. ROYCE asked the Minister of Health whether, in view of the extreme urgency for local treatment of patients, a sanction given by the Ministry to the Holland County Council to purchase Norton House, Boston, for the purpose of a tuberculosis hospital was afterwards withdrawn; whether he would give the reason for the Ministry's action; whether the contract for the purchase was completed after the approval conveyed by the Ministry's letter of May 10th last; whether, in consequence, the council was legally bound to go on with the purchase; and what steps, if any, he proposed to take in these circumstances.—Sir A. MOND replied: In view of the general instructions of the Government as to economy in public expenditure my Department has been compelled to suspend various public health schemes involving capital expenditure where an authority was not definitely committed. In the particular case referred to sanction to a purchase which had previously been given was withdrawn because on the information in the possession of the Department it appeared that the authority was not definitely committed to the purchase. It has now been ascertained that the authority is committed and the purchase will accordingly be completed.

Seamen's Insurance.

Major HENDERSON asked the Minister of Health whether he was aware that the Controller of Health Insurance promised a deputation which waited on him on July 6th that he would summon an early conference of all interests concerned to consider the advisability of improving the system of seamen's insurance; and what steps, if any, had been taken towards this end.—Sir A. MOND replied: The matter to which the hon. Member refers is now being investigated by an Office Committee appointed for the purpose. Steps will be taken at the earliest possible date to obtain the views of all interests concerned.

Pensions Surgical Hospital at Shepherd's Bush.

Major COHEN asked the Minister of Health whether it was his intention to permit the return to the Hammersmith board of guardians of the infirmary and workhouse in Ducane-road, Shepherd's Bush, which was at present being used as a special surgical hospital by the Ministry of Pensions; and whether he was aware that the Red Cross spent over £16,000 on rendering this hospital suitable for special types of cases, and that at present there was no other suitable accommodation to be obtained elsewhere.—Sir A. MOND replied: I have already written to the guardians urging them to agree to an extension of the tenancy of this institution by the Ministry of Pensions.

Licensing (No. 2) Bill.

The Licensing (No. 2) Bill as amended in Standing Committee was considered on Report, and agreed to. The Bill was read a third time and passed.

THURSDAY, AUGUST 4TH.

Medical Officers of Pensions Ministry.

Mr. HAYWARD asked the Minister of Pensions how many doctors on the staff of or employed by the Ministry, other than doctors serving part-time on medical boards, were engaged on administrative duties, and how many were engaged on the actual work of attending to patients; and what were the total annual salaries of the doctors engaged under each category, respectively.—Major TRYON (Parliamentary Secretary to the Ministry of Pensions) replied: 317 whole-time medical officers are employed at the Ministry, partly or solely on administrative duties. Their annual salaries inclusive of all emoluments amount in the aggregate to £316,255. Of these, however, 75, while holding administrative posts, are engaged for a large part of their time in visiting or examining and arranging for the treatment of pensioners, and some considerable proportion of them are, and have to be, officers with specialist qualifications. 300 whole-time doctors are employed solely on the treatment of pensioners. Their annual salaries, inclusive of all emoluments, amount in the aggregate to £220,108. In addition, the Ministry utilises the part-time services of 653 medical officers and specialists in connexion with treatment at hospitals, limb-fitting centres, and clinics, at a total annual cost of £210,558. There are also 1717 medical referees paid on a fee basis who are employed in examining and certifying patients for treatment.

Cost of Health Insurance to the Workman.

Sir ROBERT CLOUGH asked the Minister of Labour whether he could state the cost per man per week of health and unemployment insurance to the workman, to the employer, and to the State respectively?—Dr. MACNAMARA replied: The normal weekly contributions from employers and employed for Health Insurance and Unemployment Insurance, where payable, are at present as follows:—

	Health.	*Unemployment.*	Total.
In respect of men:			
Employers	5d.	8d.	1s. 1d.
Employed	5d.	7d.	1s.
In respect of women:			
Employers	5d.	7d.	1s.
Employed	4d.	6d.	10d.

In certain cases where low wages are paid, the employer's contribution for Health Insurance is increased and that from the employed is correspondingly reduced. Unemployment Insurance contributions are payable at half the above now a fine combination of discreet treatment in its broadest and best sense.

The home club is not a sanatorium in the ordinary sense; it is not a home, with the unyielding personal demands so often encountered; it is not a school with inflexible and rigid conformity to rules. It is something of all these, with social advantages adapted to the level of the innate possibilities of the epileptic. Above all, it is sufficiently in contact with outside activities to increase the epileptic's hope that he may leave it so soon as he is able to make the proper adjustments to the ordinary stresses of life.

THE MEDICAL DEPARTMENT AND MILITARY MORALE.

THE *Military Surgeon* for June prints as its first paper the Wellcome first prize essay with the title given above. The successful essayist is Lieut.-Colonel Louis C. Duncan, and it must please Mr. H. S. Wellcome, who founded the prize, to know that his liberality has evoked so very valuable an examination of the subject. Competition was open to medical officers, present or past, of the United States Army, Navy, Public Health, or Reserve services. Every officer works intuitively to improve the morale of his men, but in the United States Army this duty was specialised, and included in the staff of the American Expeditionary Force was "a morale division, with a chief, and subordinate officers in all divisions, brigades, and regiments." "An army has two supports: physical and mental (or moral). The physical support has become relatively the more important." The influence of the army medical officers on morale is great, for the conditions which govern the physical support are already, most of them, under medical supervision (such as food, shelter, clothing, health and sanitation), while to the department falls also in great measure the choice of the recruits and the elimination of the unfit: "they detect the diseased, the insane and the degenerate," eliminate "men with chronic venereal disease, drug addicts, drunkards, sexual perverts," and, an unexpected class, "the chronic grumbler." "The chronic venereal case will probably not be accepted for first-class service"; [he cannot, for instance, be a range-taker in the British Navy.] If the soldier's morale is to be maintained he must be kept in good health, and the importance of sanitary camp sites, kitchens, latrines in relation to health cannot be over-estimated. Armies have been ruined by disease alone, but the epidemics feared in the past have been conquered, small-pox, yellow fever, typhoid, and even typhus. Cleanliness of person and clothing, the prevention of lice and scabies, are being now properly studied and handled; for these the Medical Department will be largely responsible. If excellent care is given to the sick and wounded, the personal confidence of every soldier is increased and the morale of the army is exalted. Venereal disease has a deteriorating effect. The slack or slovenly appearance of a ward of venereal patients is a matter of common notice, so it is an important duty in relation to morale for medical officers to reduce venereal disease "by the utmost energy in instruction, provision of effective prophylaxis, enforcement thereof, and effective treatment."

Next come the mental factors—character. There was a great difference between the army of 1898 (Spanish-American war) and that of 1917-18. The recruits were similar, the soldiers different. In 1898 saloons. and worse places, abounded, drunkenness was common. In 1917 saloons and other vicious resorts were eliminated: men did not deteriorate in the army. Soldiers may even have been improved. Training and drill teach order, alertness, obedience, and confidence in brethren. A well-disciplined army has good morale. Discipline to-day is intelligent, and rests on an educated conviction of the need for method, regularity, and obedience. The Medical Department disciplines its own men, who are 8 per cent. of the army; further, it detects malingerers, and determines pleas of insanity, &c., and must remember not to be unduly lenient, for though discipline does not abolish mercy, justice demands punishment for crime. Officers must be leaders, better educated, more skilful, and with more initiative than their men. The medical officer knows the men individually, and should therefore be in close touch with the morale officer; he should throw himself into the sports and recreations of his unit. Games develop vigorous bodies, entertainments cheerful minds, and both are in the province of the Medical Department.

The elevating influence of sex is not to be forgotten: the Army Nurse Corps is part of the Medical Department. The Red Cross works under its direction—why not the Y.M.C.A., and the chaplains, most of whose work is in the hospitals? In the Meuse-Argonne battles, further forward than the Red Cross tents, it was to the regimental aid stations that men not actually sick, but weak and exhausted, turned for chocolates and dough-nuts, and were themselves sent back refreshed, turned again into happy warriors. The Medical Department has no direct part in winning victories, yet Napier gave the doctors credit for the victory at Vittoria, as they had sent back 5000 men from the hospitals, cured, into the line. The part, then, of the Medical Department is first to do what is its own technical duty well; secondly, to encourage all helpful agencies directed by others; thus, to the sound body the department has secured is added the quickening spirit. The whole essay will repay study.

PUBLIC HEALTH IN TASMANIA.

IN presenting the report on Public Health in Tasmania for the 12 months ending June 30th, 1920 (Hobart, 1920), Dr. E. Sydney Morris, Chief Health Officer and Chief Quarantine Officer for the State, mentions that he did not assume his position until April 27th, the duties having been performed by the assistant health officer, Dr. Arthur H. Clarke, up to that date. Dr. Morris is, however, satisfied, by the results of his personal observation, that "matters of local health administration are grossly neglected by many local authorities throughout the State," and that "the general tendency seems to be to wait until an outbreak of disease necessitates recourse to drastic and expensive remedies, rather than to carry out a systematic and steady growth of important sanitation." As Tasmania has had responsible government since 1856, it seems quite time that steps should be taken to bring about an improvement. There is still no organised method of nightsoil disposal in certain important centres (the individual householder being charged with this responsibility), and only four (out of 49) districts took samples of food and drugs to ascertain if the legal standards of quality were maintained. The Commonwealth Government have, however, intimated that they are prepared to extend their sphere of operations in regard to public health, subsidise measures of disease prevention, and "inspire and coördinate public health measures generally without infringement or transfer of the sovereign power of States," as is done in the U.S. of America. It is to be regretted that adulteration of milk is somewhat extensively prevalent; of 65 samples taken, no less than 26 were found to be adulterated or below the legal standard. The chief causes of death during the year 1919 were diseases of the circulatory system (13·57 per 10,000), influenza (10·64), nervous diseases (9·70) and respiratory diseases (9·41). There were only 11 deaths from typhoid fever (0·52 per 10,000), and not a single death from small-pox The total death-rate was 103·77 per 10,000 during 1919, as compared with 88·42 in 1918; the increase was chiefly due to influenza (10·64, compared with 1.81 in 1918), circulatory diseases (13·57, compared with 12·17), and "diseases of early infancy" (9·22, compared with 7·31). The general death-rate in 1919 from all causes was 10·37 per 1000, compared with 8·81 in the previous year: the ratio is, however, lower than in any other State of the Australian Commonwealth, West Australia having the next lowest (11·10), and New South Wales the highest (13·40), the average for the whole of Australia being 12·82.

The pandemic of influenza invaded Tasmania in August, 1919; excellent arrangements had been made in advance to cope with the situation; an amending Act had been passed, extending the powers of the Chief Health Officer; vaccine depôts and provision for free inoculation, ambulance transport, special hospital accommodation and nursing had been organised; respirators were supplied to the public, and local authorities advised through the press or by circular. When the disease actually appeared, schools, theatres, picture shows, &c., were closed; religious services in churches and buildings only allowed under certain conditions; masks were required to be worn by persons travelling inside any public conveyance where the number exceeded three; all shops (except chemists and dispensaries) were closed at 6 P.M. Extra doctors and nurses were engaged from the mainland. Only 898 cases of influenza were actually notified, being those of the C type (toxic, fulminant, or severe pulmonary); this number is therefore no indication at all of the extent of the epidemic. Dr. Morris estimates that "fully 33 per cent. of the population were affected"; this would imply some 70,000 cases, the mean population of Tasmania being estimated at 211,416. It is to be regretted that 17 towns are still without any organised sanitary service, the conditions observed by inspecting officers being "in many cases revolting." In the report of the Chief Inspector (Appendix II.) it is stated that several sanitary inspectors, who have obtained certificates of competency from the Royal Sanitary Institute, have been "informed by some local authorities that the stipends fixed by the Wages Board for expert knowledge are beyond their means of payment," and some of these officers have received notices of termination of their appointments. Such a condition of things is in the highest degree unsatisfactory.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Wednesday morning of each week, such information for gratuitous publication.*

KENNEDY, W. N. W., M.D.Edin., D.P.H., has been appointed Medical Officer of Health and Medical Superintendent of the Child Welfare Scheme for the Burgh of Galashiels.

St. Thomas's Hospital: H. L. SLAUGHTER, M.R.C.S., L.R.C.P., D. MCCLEAN, M.R.C.S., L.R.C.P., H. L. WILLEY, M.R.C.S., L.R.C.P., K. H. TALLERMAN, M.C., M.R.C.S., L.R.C.P., F. A. PHILLIPPS, M.B., B.Ch. Cantab, M.R.C.S., L.R.C.P., E. M. BURRELL, M.R.C.S., L.R.C.P., S. HARTLEY, M.C., M.R.C.S., L.R.C.P., and J. SPIRA, M.R.C.S., L.R.C.P., *Casualty Officers and Resident Anæsthetists*; C. K. J. HAMILTON, M.C., M.B., B.Ch. Oxon., M.R.C.S., L.R.C.P., E. D. GRANGER, M.B., B.S. Lond., M.R.C.S., L.R.C.P., A. D. WHITELAW, M.R.C.S., L.R.C.P., and G. A. BACK, M.R.C.S., L.R.C.P., Resident House Physicians; G. M. KENDALL, M.B. Cantab., M.R.C.S., L.R.C.P., Resident House Physician for Children; G. D. C. TRACY, M.R.C.S., L.R.C.P., P. T. LIANG, B.Ch. Cantab., M.R.C.S., L.R.C.P., D.T.M., S. H. G. HUMFREY, M.R.C.S., L.R.C.P., and F. V. SQUIRES, M.B., B.Ch. Cantab., M.R.C.S., L.R.C.P., Resident House Surgeons; E. P. BROCKMAN, M.B., B.Ch. Cantab., M.R.C.S., L.R.C.P., *Resident Orthopædic House Surgeon*; W. A. LOW, M.C., M.R.C.S., L.R.C.P., Senior Obstetric House Physician; L. B. MAXWELL, M.B., B.Ch. Cantab., M.R.C.S., L.R.C.P., Junior Obstetric House Physician; E. A. Sparks, M.R.C.S., L.R.C.P., Senior *Ophthalmic House Surgeon*; J. A. P. SHAW, M.R.C.S., L.R.C.P., Junior Ophthalmic House Surgeon; R. H. O. B. ROBINSON, M.B., B.Ch. Cantab., F.R.C.S., Eng., Clinical Assistant in Throat Department; B. SHIRES, M.B., Ch.B. Edin., Clinical Assistant in X Ray Department.

Vacancies.

For further information refer to the advertisement columns.

Barnsley, Beckett Hospital.—Jun. H.S. £200.

Barnsley County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £500.

Bath, Royal Mineral Water Hospital.—Res. M.O. £250.

Bedford County Hospital.—Asst. H.S. £150.

Belgrave Hospital for Children, Clapham-road, S.W.—Female H.P. H.S. Each £100.

Birmingham Children's Hospital.—Res. M.O. £150.

Birmingham General Hospital.—Res. Anæsthetist. Obst. H.S. H.S. Each £100. H.S.'s to Spec. Depts. £125. Res. Surg. Officer. £180.

Birmingham, Queen's Hospital.—Surg. Registrar. £100.

Rochester, St. Bartholomew's Hospital.—Res. H.S. £250. H.P. £200.

St. Mary's Hospital, Paddington, W.—Cas. Phys. £100.

Salford Royal Hospital.—Cas. H.S. £150.

Singapore Municipality.—Bacteriologist. 9000 dollars.

Swansea County Borough.—Dental Surg. £500.

Sydney University, New South Wales, Australia.—Chair of Psychiatry. £1100.

Tynemouth County Borough.—Clinical Tuberc. O. and Asst. M.O.H. £600.

Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £350.

The Chief Inspector of Factories, Home Office, S.W., announces the following vacant appointments:—Llanwrtyd Wells (Brecon); Southwell (Nottingham).

The Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for the Walsall County Court in Circuit No. 25. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than August 27th.

Births, Marriages, and Deaths.

BIRTHS.

BILLING.—On July 31st, at Denholm, Chingford, the wife of Dr. E. Billing, of a daughter.

DAVIDSON.—On July 30th, at Avonleigh, Torquay, the wife of Dr. W. Cameron Davidson, of a daughter.

KAY.—On August 1st, at The Manor House, Blakeney, Norfolk, the wife of A. R. Kay, M.R.C.S. Eng., of a son.

SINCLAIR.—On August 3rd, at 20, Riverview Gardens, S.W. 13, the wife of Neil F. Sinclair, F.R.C.S.—a son.

WOODS.—On August 4th, at St. Andrew's-street, Cambridge, the wife of R. Salisbury Woods, M.A., M.D., B.Ch. Cantab., of a daughter.

MARRIAGES.

MURPHY—SPOONER.—On August 2nd, at Bramshott, Hants, William Murphy, M.B., to Harriet Annie Spooner, of *Liphook.*

DEATHS.

MYERS.—On August 6th, at St. George's-road, S.W., Brigade-Surgeon-Lieut.-Colonel Arthur Bowen Richards Myers, late Brigade of Guards, aged 82.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

by the fact that its curve is symmetrical. The integrated equation for such a curve will be—

$$\text{Log}\ \frac{x}{A-x} = K\,(t-t');$$

where A expresses the total transformation at completion of the process, K is a constant expressing the velocity of the process, and t′ is the time at which the mass of the product equals ½ A.

CORRELATION OF CATALYTIC REACTION WITH DEFECTIVE OXIDATION IN NERVE CELLS.

Now the importance of this observation lies in the evidence that it affords that the neural process conditioning the movement is in the nature of a catalytic reaction. The researches of Mott have shown that the nervous asthenia of extreme forms of myxœdema and of dementia præcox are associated with evidences of defective oxidation processes in the nerve cells, and the correlation of the two observations affords an alluring hypothesis. The casual drawing of a straight line affords a very good example of a cortical mechanism, unchained in response to an autogenous voluntary stimulus, which runs its course without further interference. We may look to observations of disturbances of the catalytic process such as those furnished by Koch and Mann in dementia præcox to afford an insight into the asthenic types of neurosis. The slide shows the rapid exhaustion of a patient who suffered from lack of power of concentration and a distressing sense of mental fatigue when he was set to obtain a record with the Mosso ergograph. That the fatigue was not peripheral was shown by the absence of signs of muscular fatigue in response to electrical stimulation before and after the ergographic tracing. By correlating my method for the estimation of the effort tonus reflex, described in the first lecture, with observations on the squeeze exerted on a dynamometer I have noted that in such patients the bodily response of effort dies down rapidly, and simultaneously with the maintenance of the squeeze. The effort is, however, there, and this serves to differentiate this class of patients from those that we shall consider later under the category of hysterical weakness. It is in the treatment of these asthenic patients that so much harm is wrought by attempts to stimulate them to greater efficiency without first restoring their bodily condition.

NECESSITY OF CONSTITUTIONAL TREATMENT OF ASTHENIC PATIENTS.

All neurologists of experience are convinced of the great efficacy of constitutional treatment which is too often ignored by the new school of psychotherapy. I will now turn to consider those neuroses in which the predominating symptoms are manifested objectively and subjectively as an excessive response on the part of the mechanism that we have studied as the bodily reaction to nocuous stimuli. I have endeavoured to show that the bodily response to nocuous stimuli is essentially one of activity, and that the benign or agreeable stimuli are responded to by quiescence; and, furthermore, that the activity which we occasionally ascribe to the action of agreeable stimuli is really the response to those conditions of the environment that hinder their enjoyment. The time at my disposal would not allow me to attempt to consider in detail the various forms in which such a hyperexcitability of the mechanism of affection may show itself.

In the previous lecture I spoke of the caution with which we must view all attempts to attribute activity of the vegetative nervous system to the direct action of the internal secretions; it is much more promising to seek for evidence of modifications of the excitability of the autonomic mechanism as a result of long-standing hyper- or hypo-function of the endocrine system. The relations between excitability of the autonomic system and glandular activity have been more extensively studied in the case of the thyroid than in that of any other gland; I will not dwell on the well-known symptoms of hyperthyroidism; there are, however, a certain number of cases of neurosis exhibiting a hyperexcitability of the affective mechanism together with tachycardia, vasomotor disturbances, and tremor without any thyroid enlargement. There are three signs revealed by the objective examination of such cases on which I lay great stress. First, the hyperexcitability of the mechanism of affection as revealed by a study of the galvanic reflex; in these cases the skin resistance is invariably very low. This sign, though never absent in indubitable cases of hyperthyroidism, can, of course, taken alone, only amount to an objective demonstration of the hyperexcitability of the affective mechanism. The isolation of thyroxin, the active principle of the thyroid internal secretion, has permitted the quantitative estimation of the influence of the thyroid on metabolic activity. Since in cases of indubitable hyperthyroidism we invariably find the basal metabolism to be above the normal rate we cannot diagnose its presence in the absence of this sign. The determination of the rate of basal metabolism is a procedure of no great difficulty, which can be accomplished in a very short time with fairly simple apparatus. It is to be hoped that this valuable method will soon become an established procedure in the investigation of cases of neurosis. There is, however, a third sign of the existence of the condition of hyperthyroidism which is likely to prove of great value. Goetsch has devised an intradermic test that serves to demonstrate the existence of hyperexcitability of the sympathetic system. The reaction depends on the demonstration of sympathetic hyperexcitability by injection into the superficial layers of the epidermis of minute quantities of adrenalin. The test shows no more than that the sympathetic system is hyperexcitable, and furthermore it only demonstrates a hyperexcitability at the junction between the sympathetic neurone and the effector cell. It cannot, therefore, be held to be of absolute diagnostic import, any more than the exaltation of the galvanic reflex. Its importance lies in the fact that it is apparently never absent in cases of hyperthyroidism, and taken with the two preceding tests it will establish the diagnosis. As modified by Ascoli and Faggioli, the test is described thus: When 0·05 c.cm. of a 1 per 1000 solution of adrenalin is injected by a fine hypodermic needle, pushed just under the epidermis, so that its whole intradermic course is clearly visible through the skin, the resultant swelling assumes after a few minutes a dark-blue colour as if ink had been injected. The swelling then becomes surrounded by an alabaster-like halo which grows in intensity and extent, often sending out irregular shoots in one or more directions. Around the white halo appears in turn a red halo, more or less intense in colour and width. Frequently a contraction of the pilomotor muscles occurs, giving an appearance like goose flesh to the alabaster zone. This is fairly well shown by the photograph (Fig. 2). The area of goose flesh in my photograph is not, however, limited to the alabaster zone. Having reached its maximal development in half an hour, after a stationary period of an hour or so, the reaction gradually disappears, the blue spot changing to red, and leaving ultimately a small swollen papule. By using a more dilute solution, for instance, one in two hundred thousand to one in a million, the reaction is less intense but always preserves the same type. It differs, however, by the absence of the central blue spot for which a small red mark is generally substituted later on, and the red halo is not always prominent. The excitability of the subepidermal test in ordinary circumstances lies between dilutions of one in two hundred thousand and one in a million (Parke Davis phials). In some cases of disturbances of the menopause, of arterial hypertension, of Graves's disease, and sometimes in pregnancy, the excitability is increased, giving positive results with further dilutions up to one in five to twenty millions. It should be always compared with a control injection of distilled water, as some people react in a somewhat similar fashion to the water injection.

freshly hatched lice. The appearance of the unhatched nits after treatment and incubation is not altogether distinctive, but there seems to be a shrinkage in the embryo in treated cases, leaving a space between the shell and the body, probably due to drying up after death.

Comparison of Disinfestation Agents.

It would appear from the above experiments that the soap in question fulfils to a considerable extent the conditions laid down in this experiment. It appears to have a lethal effect on the embryo in the nit in a large number of cases, but more than one application seems necessary to destroy all viable embryos. It immobilises the louse, but does not immediately kill it. As all lice after treatment died within 24 hours, it is probable that it has more than a mere repellent effect. In this connexion I may add that bed-bugs immersed for one minute in an ordinary solution of the soap died immediately. It is non-toxic and non-irritant, easily applied, and has no danger attendant upon its use. It has also the merit of being within the means of the poorest and least intelligent parents of the community. Further, it may be hoped that an indirect advantage may accrue from the fact that it is a soap in encouraging parents to appreciate the general hygienic value of a weekly head-wash for their children if not for themselves.

THE TRAINING OF EPILEPTICS IN THE UNITED STATES.

IN the *New York Medical Journal* of June 15th appeared an article by Dr. L. Pierce Clark, dealing with the study and sociological training of epileptics. Dr. Clark points out the scientific need for exact observation of the peculiar physical incitors, when present, and of the psychic factors which lead to attacks of epilepsy, and the lack of suitable places where such work may be carried out. It is not possible for the trained observer to gain a proper evaluation of the character of the epileptic in surroundings that do not lend a normal setting in which the individual may display his innate temperamental defects. Large public hospitals and sanatoriums hardly contribute such precise and detailed observations as are now found necessary for exact diagnosis. Hence the need of small observation clubs and homes, for study and treatment of obscure cases. The solicitude customary in the patient's own home makes the latter environment inconvenient for trained observers; a combination is required of close observation with home environment to furnish data on the real nature of this obscure periodic disorder and its foundations in perverted and undeveloped instincts.

Epileptics Unsuitable for State Hospitals.

Epileptics placed in State hospitals for the insane disturbed an otherwise tranquil environment by their general inaptitude for socialisation. In many instances the temperamental faults of epileptics have necessitated restriction of their separate accommodation to large buildings where better personal discipline could be maintained, but reversion to this old institutional type only made matters worse, and the provision of small isolated cottages is the plan now widely recognised to be best for this class of patient.

Dr. Clark's own experience at the Craig Colony for Epileptics led him to provide each private patient with his separate nurse trainer and a tranquil existence; normal contacts were thus more or less evenly maintained, but although the life itself was ideal it seemed to encourage the main trends of the epileptic's disease. The normal residents with whom the patient came in contact either shunned the patient or over-indulged his eccentricities; and it is doubtful how closely in contact with each other epileptics may dwell without harm.

The chief aims, he thought, in group treatment of the epileptic in private practice were: (1) to establish an environment giving a fair knowledge of the life reaction faults each patient possessed; (2) an opportunity to direct proper re-education of habits; and (3) preparation of the more favourable cases to re-enter the outside world.

A First Experiment.

An effort in sociological study of the epileptic was first undertaken eight years ago on the edge of a little New England town; a group of men patients was established, each with an individual nurse trainer or attendant; but the unity between a proper home atmosphere and the actual training force was not complete, nor was the training personnel sufficiently unified to make consistent general training possible. However, daily routine, training, and observation were in force; the patients worked at gardening, woodcutting, and handicrafts, and later in the summer at gathering fruit. While this contact with townsfolk widened their interests, it lacked in social "rapport." The club being two miles distant from the town, the patients had little opportunity to engage in small village interests and activities. Thrown thus upon their own resources, the internal activity of the club group had to be expanded; but there was disinclination among the patients to adapt themselves to its environment, particularly on the part of those who were more rigid in mind and habits. Many calculated that the summer would soon pass, and that there was no use in making great efforts for so short a period.

The next step was to move the club group nearer to New York in the autumn and eliminate the faults in social grouping. Several normal individuals lived in the same house with the patients; impromptu lecture courses and new occupational interests were provided. A continued change of appeal is necessary to stimulate the rigid mental habits of the epileptic. Not a few lessened their conflicts by long walks and by occupation in the workshops.

Mixed Groups of the Two Sexes.

The next summer the New England village plan was again instituted, but with a different home management, under the nurse trainers themselves. Cottages, one for women and one for men, a short distance from each other, were secured. One dining service for all was provided. The forming of mixed groups of both sexes proved a greater incentive to spontaneous activity, occupational and social, than we had hitherto come across. The club group returned to the suburbs for the winter, where it held no new features apart from an experience of occupational outlets that withdrew much of the patient's attention from the still too rigid home management.

The following summer, the third, an abandoned hotel on the main street of the same town was taken over. Inasmuch as many patients had in the past shown considerable disinclination to follow consistent work merely for the work's sake, a system of remuneration and prize rewards was instituted, especially in gardening. A great deal of directed training had then to be undertaken by the nursing staff. Many interesting observations in this field were made; the compensation and reward principle is not a bad one, and many people, sick or well, will keep continuously employed for no other motive; in this respect the epileptic is no exception.

We soon discovered that having patients in the heart of the village life was very bad for them. Perhaps if time, patience, and extraordinary tact were employed, this principle would be no more harmful for epileptics in the United States than it is in Europe, as followed out at Bielfeldt, or in the colonisation of the insane at Ghiel in the Scottish boarding-out system. But the epileptic is not as amenable to gregarious and family life as is the chronic dement; his very temperament is opposed to this species of social treatment unless discriminating guidance and supervision are provided.

In the fourth summer it was decided to test a seaside residence. All the former features of interests, occupations, and grouping were retained, and it was found that other guests at this resort were more casual and less demanding than the people of a country town. The separate personnel of home management was finally discarded, and the club placed under one head; the social side of club activity was a great success, but consistent work and teaching were much slowed. Sea-bathing was beneficial; the patients were under proper espionage, and no accidents occurred.

The Most Recent Experiments.

The fifth summer an agricultural college town was tried, and all the patients took one or more of the summer courses; the work they accomplished did credit to all. Most epileptics possess but a third of the normal individual's physical and mental capacity, but the environment did not prove too taxing, as the summer schedule was not nearly so strict as the regular term college work.

The sixth summer it was thought that climatic conditions differing from those of the seashore experiment might have a social and occupational value in treatment. To this end the whole group was taken to the Adirondacks, and distributed in adjacent cottages; four schools were inaugurated, consisting of carving classes, Montessori and kindergarten work, æsthetic and rhythmic dancing, and English classes. Some psychotic and neurotic patients were included. The use of patients as assistant teachers increased the value of the experiment, and showed that such a plan could be made highly useful to the epileptic.

The present experiment embraces all the good points learned from previous settings; the club is established a short distance from a large town situated on the Sound in Connecticut. Personal attendants for each patient are dispensed with, group nursing and training being substituted under efficient and capable trainers. The two sexes live in the same household, which consists of children, youths, and adults as in an ordinary large family. Tennis courts, a golf course, and sea-bathing supplement indoor activities. The proper coöperation of the servants employed helps not a little. Housework, lectures, books, and magazines are available; some undertake church work, and a few have taken courses in the small business college the town affords. A club group has been formed for constructive discipline and suggestions in social activities. Thus there is recognise a difficulty is not always to be able to avoid it. The chief source of error in such investigations must always be the possibility that the subject derives his associations not from endogenous sources but from the investigator. The most casual perusal of the literature of psycho-analysis must convince any unprejudiced observer of the reality of this difficulty. We find that different investigators tend to discover widely different mechanisms of thought as lying at the root of the neurosis. The universality of the sexual basis so vehemently asserted by partisans is strenuously denied by other investigators, who themselves propound mechanisms that are not admitted universally. On any theory all these observers cannot be right, and in physical science, if we found that honest experimenters obtained consistently different results with a certain method we should not hesitate to impugn the validity of the method. A form of inquiry which involves the exclusive concentration of the mental activity of the subject on the performance of a task set to him by the observer renders him particularly sensitive to any form of stimulus that he may receive from the observer. We have seen in the preceding lectures that the expression of mental activity is far from confined to vocalisation. Movements of every variety are involved; the more obvious movements to an observer have in point of fact not been dwelt upon, that is, such movements as are evidenced by facial expression, eye movements, and the play of the pupils, for the sole reason that though obvious to the eye they present overwhelming difficulties to instrumental registration. An example from the animal world may illustrate the part that such movements play in communicating our approval or disapproval.

THE THINKING HORSES OF EBERFELD.

I know of no better example of the perils that beset this form of investigation than the story of the "thinking horses" of Eberfeld. A Prussian schoolmaster, Herr Krall, succeeded in educating horses so that they would indicate the sum or product of numbers written on the blackboard by stamping the hoof the proper number of times. Later on they acquired the power of doing divisions and extracting cube roots. They were investigated by most of the eminent psychologists of Germany and many were the papers written about their feats. The bona-fides of their master were undoubted and they would perform equally well in his absence. As time went on these animals developed superhuman powers: they would not only solve the difficult problems of the blackboard, but they would guess correctly and stamp out the number of which the observer was thinking. At this stage they were investigated by Stumpf; he confirmed their marvellous powers of guessing the numbers thought of, and then proceeded to test their ability when blindfolded. The horse did everything it could to see the observer from under the bandage; when it succeeded in doing so the answer was right, but when the blindfold was effective it was generally wrong. That solved the mystery; Stumpf found that, in common with every observer, when the number that he had thought of was stamped out he made a little involuntary gesture of assent which the quick eyes of the horse noted. I have often repeated the same experiment, taking the part of the horse myself, and so long as the subject is innocent of the method employed I have seldom failed. To an experimenter conducting an analytic examination no stimulus word can be totally without affective import, be it the expectancy of a result or the recognition of its futility.

RESPONSIVENESS OF THE SUBJECT OF INQUIRY.

The subject is dissociated from all other stimuli than those communicated by the observer. He is warned to respond without self-criticism or hesitation. If with a casual fixation of attention it is easy to repeat the experiment of the Eberfeld horse under the conditions of a psycho-analytical investigation there must be many signs such as the inflexions of the voice and the play of the features, that it is impossible to control. In such a responsive attitude on the part of the subject wilful deception of course plays no part. Evidence of the extent to which the responsiveness of the subject can be raised under appropriate conditions can be found in the Proceedings of the Society for Psychical Research. Whatever be the eschatological value of these documents they certainly contain a mine of information to the student of abnormal psychology. The alertness with which almost imperceptible hints are adopted, the amazing accuracy with which the observer's mind is interpreted by perfectly honest subjects who have placed themselves as purely receptive instruments in the hands of the observer whilst under the belief that they are giving utterance to the thoughts possessing their brain, must give pause to anyone who notes the conditions under which analysis is carried on. Even when suggestion is discounted it is impossible to ignore the part played by the analyst in the interpretation of the results. I have sufficiently dealt in a previous lecture with the incommunicable uniqueness of states of feeling. It is for these and similar reasons that, in so far as it has appeared to be desirable to inquire into the associations connected with any particular phase of conduct, I have confined myself to a very superficial examination that readily permits of an objective control. The patient is allowed to tell his history without interruption or question whilst a continuous record of his skin resistance to a constant current is photographically recorded on a roll of bromide paper. The observer sits behind him, and the main headings of his discourse are taken down on a sheet of paper ruled so as to allow the time at which any statement was made to be compared with the timed record of his resistance. I have made many such records and they form curious psychological documents.

INCONSTANT REACTION OF THE VEGETATIVE SYSTEM.

It is by no means those statements to which the patient appears to attach most importance that furnish evidence of an affective response; obvious attempts to achieve pathos may leave the galvanometer unmoved, whilst the narration of some less prominent incidents which reveal the general orientation of the patient's attitude will evoke a well-marked galvanic reflex. Even with such precautions the results obtained must be interpreted with considerable caution. Sherrington and Grünbaum have shown that stimulation of a cortical area after an interval by no means invariably evokes the same form of response, and we may interpret this as a physiological demonstration of the fact that our reaction at any given time to a stimulus is determined to a great extent as to its form by the particular equilibrium in which the stimulus finds the nervous system. Still more so is this true of the mechanism of the affective response. The vegetative nervous system does not always react in the same fashion to the same type and intensity of stimulus. I was able in conjunction with Symes to furnish an experimental demonstration of this fact in connexion with the sympathetic innervation of the bronchial muscles. When the neuro-muscular junction of the sympathetic nerve-supply to the bronchiolar muscles is stimulated by the same dose of adrenalin a precisely opposite type of response may be elicited, according to the condition in which the stimulus finds the bronchiolar mechanism. If the bronchioles be constricted the stimulus will cause dilation; on the contrary, when the bronchioles are dilated sympathetic stimulation will cause constriction (Fig. 3). A very little

Antagonistic action of adrenalin on bronchioles. Firstly, when dilated; secondly, when constricted.

Croonian Lectures

ON

THE OBJECTIVE STUDY OF NEUROSIS.

Delivered on June 21st before the Royal College of Physicians of London.

BY F. L. GOLLA, M.B. OXON., F.R.C.P. LOND.,
PHYSICIAN TO ST. GEORGE'S HOSPITAL.

LECTURE IV.[1]

IN the preceding lectures I have endeavoured to give some account of the objective features of the fundamental mechanisms of cerebral activity. I propose in this concluding lecture to indicate in what fashion objective psychology may be applied to the study of the neuroses. We have seen that the mechanisms of cerebral activity are fundamentally of two characters. In the first place the discriminatory cortical activity finds its expression in the movements of the voluntary nervous system—that is, in actual muscular movement and in the kinæsthetic representation of such movements in the motor cells of the cortex. In the second place the general reactions of the organism to stimuli that tend to destroy or impede functional activity find their expression in the movements of the thalamic system and effector organs. Since the nervous system is an instrument of movement, and nothing else, we should be prepared to find that a certain group of the functional disturbances that we term neuroses would be the expression of some chemico-physical changes affecting movement of the neurones generally. Our knowledge of the chemico-physical processes that constitute activity of the neurones is as yet too incomplete to furnish a secure basis for a descriptive pathology.

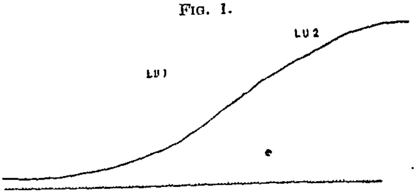
THE FUTURE TASK OF NEUROLOGY.

At present we rely chiefly on deductions from the similarity to certain aspects of neurosis in the behaviour of the organism when functional activity is disturbed by toxic substances, whether ingested or manufactured, in the body. The study of these physico-chemical disturbances will be the great task of the neurology of the future. The researches of Sir Frederick Mott and his pupils have broken new ground in the elucidation of the micro-chemical signs of disturbances of the function of the neurones, whilst the work of Pighini has opened the path for chemical investigation through the study of metabolic disturbances. The policy of the London County Council in giving effect to the scheme endowed by the late Dr. Maudsley in founding a school and hospital for the study of the earliest stages of nervous disturbances is justifying itself by the additions now being made to our knowledge of the chemical and physical changes that express disordered function of the neurones. The work of Koch and Sydney Mann performed in the L.C.C. laboratory suggests that the general bodily deficiency of oxidation activity demonstrated in dementia præcox is the interpretation of the micro-chemical changes shown by Mott to be characteristic of the nerve cells in this disorder. Just as such an advance in our knowledge of the physical basis of this form of insanity must once and for all dispose of the theories of its psychogenic origin such as that advanced by Jung, so we may hope that by similar methods the physical basis of the asthenic forms of neuroses may be established.

There is, indeed, a certain body of physiological evidence in favour of the view suggested by the micro-chemical methods of Mott and his pupils, that the processes of nervous activity are of the nature of a catalytic phenomenon. Brailsford Robertson repeated an earlier observation by Loeb and Koryanyi on the *determination of the curve of the velocity with which a simple movement of drawing a straight line of indeterminate length is performed.* Robertson ruled straight lines with a form of apparatus allowing the construction of a curve of the velocity with which his pencil travelled at any moment of the drawing. The pencil, which was in reality a metal stylus connected with one arm of the circuit of a battery activating a Deprez signal, travelled across a number of longitudinally arranged alternating slips of ebonite and copper. The copper slips were each connected with the other arm of the signal circuit. When the stylus travelled over one of the copper slips the circuit was closed and the signal made a mark on the smoked paper of a drum rotating at uniform speed. Since the copper slips were equidistant it is obvious that by measuring the distances between the signal marks on the drum it was possible to ascertain the velocity with which the stylus moved at any point of its journey. These data furnished a curve of the velocity which showed the following characteristics: The velocity underwent progressive acceleration; beginning slowly, the velocity of the stylus reached a maximum and then again diminished, so that the commencement and termination of every curve was asymptotic.

In order to verify the conclusions of Robertson I arranged an endless band of linen revolving with constant velocity round two drums set horizontally at a distance of about two feet apart. The band of linen was a yard in width. Midway between the two drums it passed over a third roller. The apparatus was covered by a board except for a gap about 2 inches wide just over the middle roller. A line of arbitrary length was ruled with a pencil along one edge of the gap and the quickly moving band did not allow the curve traced to be followed by the eye. No attempt was made to determine voluntarily either the velocity with which the line was drawn, or its length, so long as it was within the limits of the band. Lines were drawn both towards and away from the body, using movements of the whole arm, elbow-joint, or wrist in order to eliminate the possible influence of the type of movement employed on the form of the curve. When the band was removed the resulting curves in every case agreed with that constructed by Robertson (Fig. 1). Now Robertson has shown that such a curve is typical of an autocatalytic process—that is, a chemical process of such a nature that it is catalysed by one of the products of reaction; in such a case the commencement and termination of the velocity curve is asymptotic.

FIG. 1.



Curve traced by drawing a straight line across a rapidly-moving linen band. *Time below in 1/100 second.*

Examples in chemistry of such autocatalytic reactions, in which one or more of the products of reaction accelerate their progress, are furnished by the hydration of methyl acetate or the hydrolysis of cane sugar at 100°. In such a reaction a point must be reached when the decrease in the active mass of the reacting substance balances the increase of the active mass of the catalyser. A catenary reaction is the only other type of reaction that will show a similar acceleration, but the autocatalytic reaction is distinguished constitute a method of expression primarily for egoistic and secondarily for social needs which has been conditioned by an organic disability of the mechanism of affection. Another cardinal symptom of the hysteric is referable to the same organic disability. All writers on hysteria have emphasised the abnormal suggestibility of the hysterical subject. Suggestibility has been defined by McDougall as a process of communication resulting in the acceptance with conviction of the communicated proposition in the absence of logically adequate grounds for its acceptance.

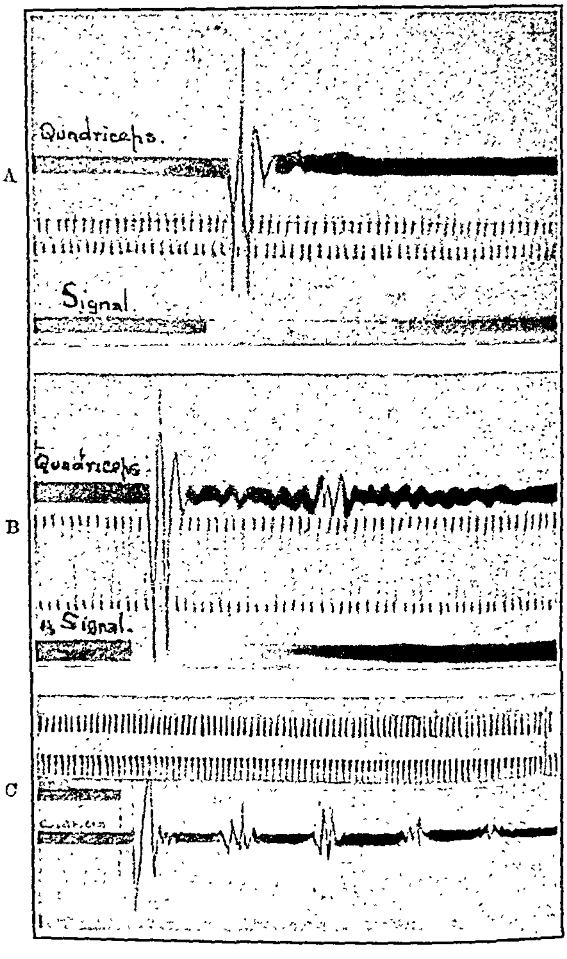
---

[1] Lectures I., II., and III. appeared in THE LANCET of July 16th and 30th and August 6th, respectively.

The destructive criticism of logic by the pragmatists has taught us one thing—that is, that no judgment is without its affective side, a truth which, though by no means new, since it is implicit in the revolt against formal logic which began in the psychological studies of Fries and Herbart, is still occasionally forgotten. Our strongest bond with reality is that of the feelings which constitute our strongest defence against the irrational. Mind dissociated from feeling is mind very much at the mercy of any suggestion. It is the bodily reaction against a suggestion that is in discord with the general tendencies of our activity that is the real guarantee against its acceptance. It is just this defence that the hysteric lacks; to a greater or less extent his activities can be unduly influenced both by autogeneous and heterogeneous suggestions. In other words, the innate and habitual pattern reflexes, having lost the mechanism of bodily reaction by which they reply to stimuli tending to interfere with their activities, are no longer the potent protective system that they constitute for the normal man and can be displaced or dissociated by any new stimulus of sufficient potency. Great as has been the work of Babinski and his school in demonstrating the mimetic nature of hysterical symptoms, it has been needlessly impaired by the criterion that they have adopted of what constitutes a hysterical symptom. Limited by the subjectivism that defines hysteria as only differing from fraud in its moral aspect, they decline to consider as hysterical any symptom that cannot be produced by an effort of will. This is a return to the subjective method par excellence. Of will and its limitations we have no objective knowledge, and as Spinoza once said: "No one has yet learned from experience what the body regarded merely as a body is able to do in accordance with its own natural laws, or what it cannot do. For no one knows enough about the constitution of the body to examine all its functions."

The study that we have just made of the movements manifested during cerebral activity has revealed a series of motor, circulatory, and glandular reactions, which, though not capable of being directly influenced by volition, are in their totality the expressions of volitional effort. Owing to his dissociation from states of feeling the hysteric appears to readily assume that state of muscular hypertonicity which we have observed as an accompaniment of concentrated effort, and the reflex response to certain stimuli is in consequence greatly exalted. The response to auditory stimuli frequently takes the form of an exaggeration of the normal "start." I have pointed out that the latent period of the start in man is extremely short, not much longer than the 0·05 second found by Sherrington in the decerebrate animal and the exaggerated start of the hysteric, having the same latent period as that of a normal man, a voluntary origin must therefore be ruled out. Even more striking is the exaggeration of the knee-jerks. The response may not only be increased but followed by a series of irregular clonic contractions—which may, however, be readily differentiated from the true quadriceps clonus of a lesion of the pyramidal tract when recorded by the oscillograph or the string galvanometer (Figs. 4). As Wertheim Salomonson has pointed out, the electromyogram of the true clonus points to an origin different from that of the spurious hysterical clonus. None of these phenomena are directly referable to voluntary activity, but they are consistent with the supposition that the patient is in the same state of muscular hypertension as a normal person whose whole organism is concentrated on a particular voluntary effort. I have occasionally succeeded in obtaining myograms exhibiting a similar functional clonus from normal subjects concentrating all their attention on squeezing the dynamometer. It is generally accepted that when a case of hysteria is characterised by some paralytic or motor symptom which simulates the effects of a definite organic disturbance it is always possible to differentiate between the hysterical symptom and the organic one by the fact that such subsidiary mechanisms as would be certainly affected in organic lesions are not affected in the case of hysteria. In hysteria, owing to the ignorance of the subject of the physiology of the symptom mimicked, the affection of these subsidiary mechanisms would never be suggested to him.

FIG. 4.

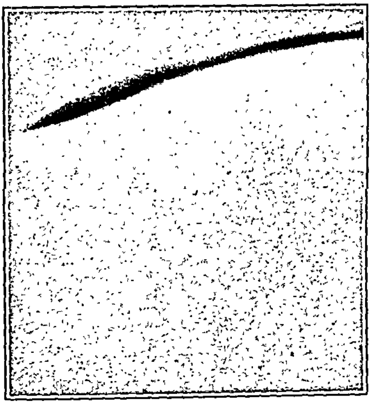


Electromyograms taken with Bock-Thoma oscillograph.
A, Normal knee-jerk. B, Hysterical knee-jerk, with functional patellar clonus. C, Knee-jerk, with patellar clonus in spastic paraplegia.

Whilst in the great majority of cases this rule holds good, and is indeed sufficiently constant to be our standard method of differentiation between organic and functional disease, it is not quite universally true. It would appear that certain mechanisms are so closely allied with the normal exercise of particular functions that although their existence and connexions are unsuspected by the patient it is impossible for the main function to be suspended without their being also affected. Hurst has pointed out that in cases of total hysterical deafness the start or jump to a loud sound may be suppressed. Such suppression

Using this technique in preference to that of Goetsch I have obtained positive results in all those of my cases exhibiting indubitable symptoms of hyperthyroidism with hyperemotionalism, and in some dozen cases occurring at the climacteric in which flushing, giddiness, and nervous tremors were complained of, and which showed an excessive galvanic reaction. So far the evidence seems to be clear that hyperactivity of the mechanism of affection is associated with the frequent occurrence of hyperactivity of the thyroid. That thyroidism is not the only cause is certain; we find such hyperexcitability associated with other bodily states, in diabetes, at puberty, at the climacteric; it can be produced artificially by many drugs such as adrenalin. That hyperthyroidism can be conditioned by the environment is certain; cases occurred during the war in which pronounced symptoms of Graves's disease were noted within a few days of exposure to the strain of action; but I have already sufficiently emphasised in my first lecture that considering the multitudes subjected to like conditions we cannot but come to the conclusion that the very small number of men affected had a pre-existing abnormality of the thyroid function. There is good reason to believe that a long-continued excitation of the affective mechanism may lead to a temporary hypertrophy of the thyroid activity; this fact was demonstrated by French observers in the civilian population of bombarded towns, but where there is no pre-existing state of organic instability such states are not lasting. The implantation experiments of Steinach have demonstrated that excitability of the affective mechanism subserving sexual activity may be directly influenced by the internal secretions of the gonads.

FIG. 2.



Intradermic test for sympathetic hyperexcitability, showing the needle track and an appearance like goose flesh in the alabaster zone.

PROBLEM OF RELATIONSHIP OF INTERNAL SECRETIONS TO NERVOUS MECHANISMS.

Our knowledge of the relationship of other internal secretions to nervous mechanisms is as yet too scanty for discussion; such secretory activity may well be the determining factor in unloosing innate types of nervous mechanism or instincts—e.g., the unchaining of the dormant maternal instincts in the capon. Some of the wildest imaginings of the novelist may, indeed, have a basis in physiological fact. It is by no means inconceivable that latent innate reflex patterns may occasionally be aroused without any form of suggestion by knowledge or example on exposing the individual to the appropriate environmental stimulus; examples are not wanting in the study of animal behaviour. The mention of these abnormalities of instinctive behaviour leads us to the consideration of another type of neuroses, in which the distinguishing feature is some line of conduct, which is at entire variance with the demands of the environment and which we can recognise to be related to the affective symptoms that are aroused by any interference with it. We have already seen that it is hopeless to seek in such conditions for associations between the primitive innate mechanism and conscious discriminatory processes. These types of instinctive behaviour may occasionally have been re-awakened by the environment, or they may owe their appearance to certain structural abnormalities which constituted the primary stimulus at a period when the innate mechanism was not at variance with the more primitive conditions under which the ancestral stock lived. It is only the manifestation of primitive instincts that are ill-adapted to the environment which is of importance to neurological medicine. Similar in their manifestations to the instincts, and yet so different in their origin, are the conditioned reflex patterns or habits. Both types have, as we have seen, this in common, that interference with their free activity is responded to by the nervous system in the same fashion in which it responds to a nocuous stimulus which tends to injure or impede the normal course of vital activity. The resultant powerful bodily reaction with its disagreeable affect may on frequent repetition condition a new defensive habit mechanism of which certain writers who prefer the terminology of dynamic symbolism speak of as repression by a censor whose habitat is the unconscious. In normal people, whose mechanism of affective reaction is not hypertrophied, such unfitting instinct and habit mechanisms will cause but little disturbance. In those whose affective mechanism is hyperexcitable the disturbance produced may be so profound as to affect every manifestation of conduct. What is in some men an excentricity constitutes in others a neurosis.

PROBLEM OF STIMULI ORIGINATING HABITS.

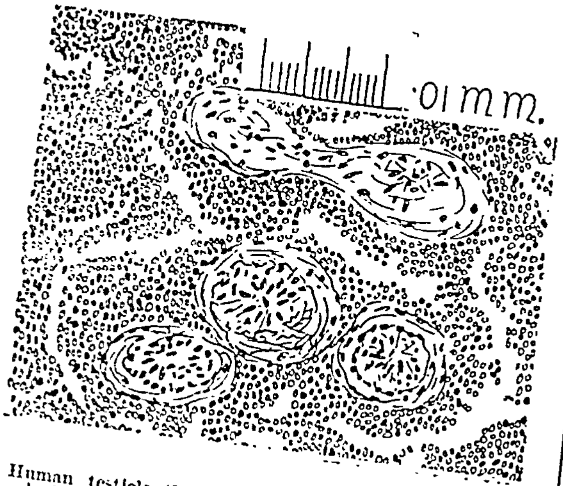
Now though to endeavour to discover what are the primary psychical correlatives of an instinct mechanism is to attempt the impossible, to determine the form of stimulus that originally conditioned a habit is a more hopeful task; by doing so we may be able to introduce the links of the habit mechanism to other and more rational associations and so to disintegrate its power. It is this task that is attempted by those who try to arrive at the original condition by the analytic method. I do not propose to discuss the utility of the psycho-analytic method. That it has given much valuable information in the realm of psychology is beyond question; whether its application in the field of medicine has yielded advantages outweighing its manifest drawbacks is a question about which there is much difference of opinion. An attempt to discover the associations presumably existing between different processes of cerebral activity and a particular disordered mechanism by learning from the patient what he can tell of the associations which are most readily evoked by an appropriate verbal stimulus is of course a perfectly legitimate objective method, but in an attempt to base our study of neurosis on purely objective investigations we are bound to scrutinise very carefully the validity of the means which we adopt.

DIFFICULTIES OF INQUIRY BY METHOD OF ASSOCIATION.

There are several factors involved in an inquiry conducted by the method of association that must prove to be very grave difficulties in the path of anyone seeking to conduct investigations in the spirit of objective science. These difficulties are probably quite well realised by the many acute intellects that have busied themselves with the analytic method, but to found the spermatic vessels too short to allow of the testis being placed without tension in the scrotum. True crural ectopia of this kind has been denied to exist by Eccles,[2] but a similar case to mine was reported by J. A. C. Macewen.[3]

The problem of bringing down by operation a testicle arrested in the inguinal canal is, to my mind, insoluble, if it is to be effected without damage to the gland. It is, indeed, possible to bring down and fix in the scrotum many testicles by adopting the procedure recommended by Bevan.[4] The essential step of Bevan's operation is the division of the spermatic vessels, it being maintained that the artery to the vas is capable of carrying sufficient blood to the testicle to keep up its activity. Bevan devised his operation after a consideration of the work of J. Griffiths,[5] who, after tying the spermatic artery and veins in the dog experimentally, came to the conclusion that one of three results followed: (1) atrophy, (2) suppuration and necrosis, (3) no interference with the normal functioning of the organ. In operations upon man suppuration and necrosis should not occur. It was due to sepsis in the experimental work. On carefully reading Griffiths's paper it will be found that in only one animal did no alteration in function or structure occur and, in making a post-mortem examination, he was able to demonstrate by injection that the circulation through the spermatic artery and veins had been re-established. Now this re-establishment of the circulation cannot possibly take place when Bevan's operation is performed on man because the spermatic vessels are not only ligated but cut across. Mixter[6] has reported that Bevan's operation is usually followed by great atrophy of the testicle, and with this statement my own experience is in agreement.

FIG. 1.

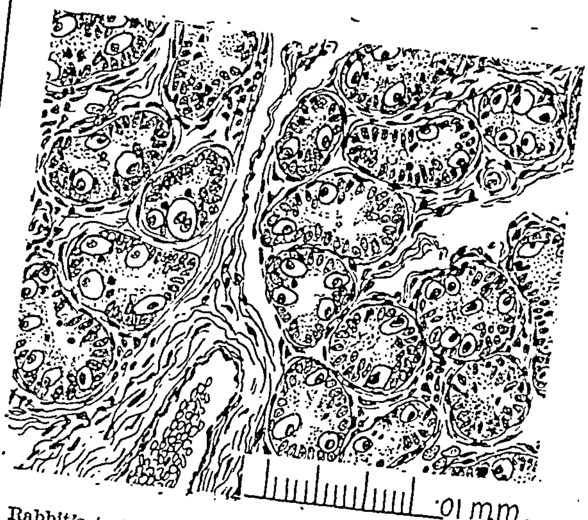


Human testicle three days after Bevan's operation had been performed, showing hæmorrhagic infarction and necrosis of tubules.

In 1913 I performed Bevan's operation on an adult man with an inguinal testicle and hernia. In suturing the wound the superficial epigastric vein was transfixed. The suture tore a hole in the vein and maintained the patency of it, and bleeding from the wound was continuous. Three days later the wound was opened up. The superficial bleeding point was not thought to be sufficient to account for so much hæmorrhage, so I examined the ligated divided ends of the spermatic vessels. There was no hæmorrhage from them. The testicle was removed and the inguinal canal sewed up completely. The testicle was sectioned and Dr. E. H. Kettle's report was as follows: "The condition is practically one of infarction. In the hæmorrhagic areas of the testicle the tubules are necrotic and structureless and stain a faint pink. Shadows of nuclei can be seen. The tubules are separated from one another by blood. In the globus minor the tissues are œdematous and infiltrated with blood and there is some angioblastic reaction."

Fig. 1 is a line drawing of the section and it shows the degenerated tubules and infiltration with red blood cells. Looking at this it is difficult to conceive that the gland would ever recover sufficiently to perform any function spermatogenic or internal secretory in nature. An organ which was able to produce and maintain the male characters or, at least, to make its contribution towards this end had been converted by my operation into a useless appendage. My conviction is that this is the usual result of performing Bevan's operation.

FIG. 2.



Rabbit's testicle four months after orchidocœlioplasty.

C. Davison[7] published an ingenious method of operation, the essential feature being the division of the deep epigastric artery and internal inguinal ring, and the flattening out of the small angle formed by the spermatic vessels as they run from the abdomen to the inguinal canal. Unfortunately, this does not increase the useful length of the spermatic vessels sufficiently for it to be of great use in the average case. Walther's operation, which has been adopted by Mr. Philip Turner, is useful in just those cases where the deficiency in length of the spermatic vessels is not a great obstacle.

Orchidocœlioplasty.

The alternative to placing the testicle in the scrotum—namely, replacing it in the abdomen intra- or extra-peritoneally—has not received very much attention from surgeons. The objections urged against it are: (1) that sections of retained testicles with rare exceptions show little evidence of spermatogenesis; (2) that testicles placed in the scrotum frequently increase in size and function normally; (3) that, experimentally, abdominal replacement causes testicular atrophy.

It is true that the retained testicle maintains its fœtal characters histologically. This may be not because of its position but because of the congenitally deficient impulse to development. The fact that testicles placed in the scrotum frequently develop normally is simply an expression of delayed development. A certain number of retained testicles descend late and become normal organs finally.

observation of our own feelings reveals a similar process. A stimulus that has evoked a pleasurable feeling may on repetition prove disagreeable, and vice versa: "Nessun maggior dolore che ricordasi dei tempi felici nella miseria." It by no means follows that a stimulus evoking a galvanic response indicating its "nocuous" nature always did so. As a method of therapeutics the attempt to disintegrate the aberrant mechanism by the introduction of fresh associations, if the contention as to the organic disturbance underlying the neuroses be correct, can only claim to be a form of symptomatic treatment. In the absence of efficient radical treatment symptomatic treatment is justified, so long as it is not mistaken for a process of radical cure. It is as symptomatic treatment that the methods of psychotherapy must justify themselves, and there can be no greater disservice rendered to its claims than the talk of "cures" evidenced by the sublimation or removal of certain symptoms of a particular neurosis.

HYSTERIA.

So far I have dealt with the fundamental characters of neurosis in which the physical disturbance is manifested by a hyperactivity of the mechanism of affection. I will now turn to a type of neurosis in which I have reason to think that the fundamental disorder is an impairment of the activity of the mechanism of affection; the forms of neurosis that fall under this definition are those designated as hysterical or pithiatic. The conception of the nature of hysteria has undergone a radical change in recent years. The supposed stigmata that seemed to constitute the neurosis an organic disease have been discarded one by one. Under the ægis of Babinski we have learnt to eliminate all symptoms from the clinical picture of the neurosis that are not entirely under the control of the will, until we have reached a point when our knowledge of hysteria may be summed up in Babinski's famous dictum—"Entre l'hystérie et la fraude il n'y a qu'une difference d'ordre morale." Hysteria, then, can only be distinguished from conscious simulation by a purely subjective criterion; it may appear to be a retrograde step to return to the old search for organic disturbance after our symptomatology has been carefully purged of the so-called stigmata, which have one after another been shown to be simply the response of the patient to auto- and hetero-suggestion. If, however, the view that a neurosis is the expression of an organic disturbance is to be consistently maintained, an attempt to demonstrate the existence of signs of such disturbance in hysteria is a logical necessity. The implications of the view propounded by Babinski do not seem to have been clearly recognised. Starting with a purely objective analysis of conduct, he finishes by abandoning all attempts at an explanation in terms of neuropathology and refers us to a purely subjective standpoint. Any attempt to understand hysteria must be founded on some knowledge of the general orientation of the behaviour of the hysteric before his conduct brings him into contact with the physician. Such knowledge is rarely directly available to the specialist; it may more often be gleaned from information supplied by the family doctor or by intelligent relatives. The picture obtained from these sources is that of an egocentric individual without strong or durable emotions, though very anxious to impress the outer world with the gravity and intensity of his experiences. Always more ready than a well-bred person should be to impress his fellows, he will not willingly apply himself to any task involving strenuous exertion, fatigue, or danger. The total personality conveys an impression of flimsiness. He appears to be a very different person to the volcano of ill-suppressed sexual passions that some writers on psychotherapy have portrayed. The symptoms of hysteria convey to the observer a certain general impression of what can be called theatricality—though possibly the stage ill deserves such a comparison. The necessity under which the cinematograph actor finds himself of conveying his mental states to the audience by emphasising all the mechanisms of expression has much in common with the conduct of the hysteric. Such vague impressions might lead us to look for indications of enfeeblement of the mechanism of affection which reinforces and protects the general tendencies of normal conduct. In 1918 I had the opportunity of examining all the cases of neurosis that passed through the Maudsley Neurological Clearing Hospital, which at that time had over six hundred beds. I found that the large class of patients exhibiting those motor and physical symptoms which constitute the hysterical syndrome could be readily differentiated from other types of neurosis by the extraordinary depression of the galvanic response to any form of stimulus. Such patients would start or tremble at a loud noise or painful stimulus, when a normal man would hardly budge, but the galvanic response would be either absent or less than normal. Though they might talk of great emotional perturbation there was no corresponding galvanic reflex. The *mise en scène* of the galvanometer room seemed to be extremely conducive to the exhibition of hysterical crises, and I had the opportunity of observing the galvanic reflex during many such scenes. One young soldier suffering from a hysterical contracture of the foot broke down during an examination; tears rolled down his cheeks, he addressed his dead brother in language savouring of a South London melodrama, he asked why he himself had not been killed in his brother's place so that the favourite son might have been left to comfort his poor old father, and all the time whilst he wailed and wept the spot of light from the galvanometer mirror remained steady. In my second lecture I pointed out that in the recitation of dramatic poetry the counterfeiting of rage or grief, no matter how dramatically performed, is unaccompanied by the electrical signs of activity of the affective mechanism. In these observations we have, I think, the key to hysterical behaviour. It is purely imitative. I published these results in a very condensed form at the meeting of the British Medical Association in the autumn of 1918, and since then have seen no reason to modify the conclusions that I then formulated. I not only found that the response to the alleged emotional states is absent but that the hysteric reacts subnormally to all forms of adequate, that is nocuous, stimuli. We are therefore entitled to assume that the activity of his mechanism of affection is subnormal. In the second lecture I demonstrated that a study of the time relations of the galvanic and other forms of response to nocuous stimuli shows that the stimulus is recognised and elicits an appropriate cerebral response an appreciable time before the bodily mechanism of affection reacts. We have, in fact, a kind of dualism—on the one hand the discriminatory mechanism associated with intelligent behaviour, and on the other the reaction of the organism as a whole to a nocuous stimulus. Herein lies the explanation of hysterical conduct. The hysteric is as capable as a normal man of recognising that the situation in which he finds himself is one of potential peril or discomfort, he can respond immediately to the situation by an appropriate cortical reaction; but if the stimulus be continued his activity lacks the reinforcement supplied by bodily reaction. To determine his line of conduct a representation of the situation is necessary, and such a representation must normally involve the activity of the mechanism of affection, since in no other way can the unpleasantness of the situation which reinforces the intellectual appreciation of its danger be recognised. Deprived of this determining force his reaction to the situation will be at the mercy of any casual stimulus. We have had objective evidence that the affective reaction fails him; he has then recourse to other forms of expression more or less distantly associated with the feeling of unpleasantness. The association of bodily ailments with the feeling of distress will most readily furnish the mechanism by which the patient endeavours to represent to himself and to symbolise to the external world the fact that his activities are impeded or threatened by some nocuous influence in the environment. Hence the hysterical symptoms really more in length, folded repeatedly on itself, with a multitude of sharp flexures. Thus a great vis a tergo must be required to overcome the resistance of this intermediate path. Is the secretory pressure in the seminal tubules sufficiently high for this purpose? I think not. The delicate cells here present, undergoing frequent mitoses, give anything but the appearance, in microscopic section, of being subjected to such constant pressure. The necessary force I believe is obtained by contractions of the cremaster muscle on the soft testicular and epididymal substance. If this is so we have an explanation why, when an abdominal replacement is performed, the external secretory cells are unable to function against the great resistance of the intermediate path. The internal secretory cells, whether they be in the interstitial tissue or reside in the tubules, are not so affected, their secretion finding outlet through the circulation.

FIG. 5.

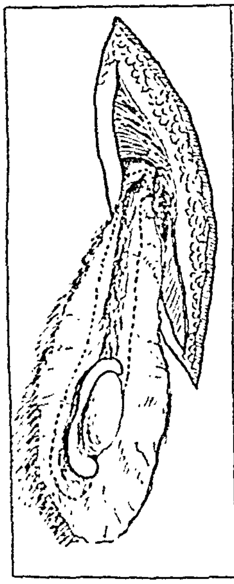

FIG. 6.

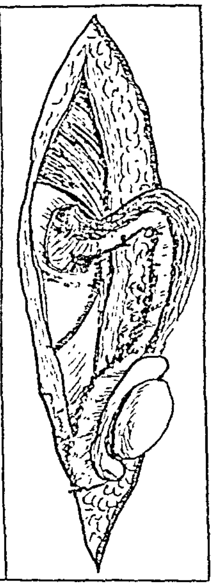

FIG. 5.—Diagram to show how the tunica vaginalis is cut when an abdominal replacement of the testicle is to be made.

FIG. 6.—Diagram to show how the tunica vaginalis is sewn back so as to form a small peritoneal fold behind the cord. The peritoneal opening can then be sutured without any danger of compressing the cord structures.

The practical application of this knowledge amounts to this, that after an abdominal replacement no hope of the development of the power of spermatogenesis can be indulged in, but, on the other hand, it can be assumed that the internal secretory function will be carried on as usual. When the surgeon is confronted with the choice between a Bevan operation and an abdominal replacement there can be no question that the latter is the proper choice, for it is unlikely that after Bevan's operation any function at all will remain to the gland. But there is another possibility to be faced. An inguinal testicle may only be delayed in its descent and be destined to continue its passage ultimately into the scrotum and to reach full development. If such a testicle were placed in the abdomen all hope of spermatogenesis would be lost. To minimise this risk it is desirable to postpone operation until 8 years of age or even 12 years unless there is some other factor indicating earlier measures. The chief factor determining early operation is the presence of pain either due to partial torsion or to muscular traumatism. Both these factors cause fibrosis of the organ and prevent its development. A bubonocele is not an indication in itself, and in any case up to four years no truss should be worn. But if there is a large hernia, or if symptoms of strangulation occur at any time, early operation is imperative, and abdominal replacement should be the method of choice.

In older children and adults it is easy to separate the hernial sac from the cord structures and to make an adequate extraperitoneal nook in the iliac fossa for the reception of the gland, but in young children the peritoneal sac is so exquisitely thin and frail that its separation from the spermatic cord becomes almost impossible. In such patients an intraperitoneal replacement is done. The procedure is as follows:—The sac is split up to the internal ring; at this level two-thirds of the circumference of the sac are divided transversely, and the incision is carried down on each side of the cord at about one-third of an inch distance from it (see Fig. 5). Behind the cord and epididymis the two cut edges are sutured with fine catgut, so that both these structures become surrounded completely by peritoneum, and at the aperture of communication with the abdomen an artificial mesorchium for the emerging cord is made (Fig. 6). The testicle can now be replaced in the abdomen and a satisfactory suture of the aperture of emergence made without there being any danger of injuring the spermatic vessels by the stitching. The inguinal canal is closed as in the radical cure of hernia.

Conclusions.

1. The future treatment of the incompletely descended testicle will lie in the direction of furnishing the missing stimulus to full development.
2. The ectopic testicle can usually be transferred to the scrotum without endangering its future growth.
3. It is not possible to implant a testicle arrested in the inguinal canal into the scrotum without damage to the organ.
4. The replacement of such a testis into the abdomen will destroy any prospect of ultimate spermatogenesis, while it will not interfere with the internal secretory function. The seminal tubules are unable apparently to secrete against the high resistance imposed by the passage through the coni vasculosi and epididymis, unless they are aided by the contractions of the cremaster muscle.
5. Early operation is not recommended. An uncomplicated bubonocele is no indication for operation, but attacks of torsion or strangulation are.
6. When it is impossible to bring down the testicle into the scrotum without endangering its blood supply, orchidocœlioplasty is preferable to removal. The technique of the operation is indicated.

GASTRIC OPERATIONS:

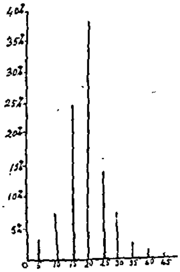
A NOTE ON ONE HUNDRED CONSECUTIVE CASES.

BY L. E. BARRINGTON-WARD, M.CH., F.R.C.S. EDIN., F.R.C.S. ENG.,
SURGEON, GREAT NORTHERN CENTRAL HOSPITAL AND HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

GASTRIC surgery has passed through several phases. A few years ago the last word seemed to have been said in the surgical treatment of disorders of the stomach. More recently a feeling was abroad that all was not well with gastric surgery, that gastro-enterostomy was a bad operation, that excision of ulcer was disappointing, and that, bad though the results of the physicians were, the results of the surgeons were even worse. More recently still, as numerous articles and discussions have shown, opinion has veered again and surgeons at any rate are well pleased with their results. A variety of remedies for one disease suggests inefficient treatment, and the varied procedures invented for the treatment of gastric ulcer might suggest that surgical treatment was unsatisfactory. As in everyday life, so in surgery, there have been waves of fashion, and the treatment of gastric ulcer has been especially at the mercy of the prevailing fashion. The writer believes that the great majority of operations by capable surgeons for lesions of the stomach are satisfactory and that the failures are due to the adoption of the wrong operative procedure. The essence of surgery is experiment—much of an involuntary mechanism does not, however, appear to be true of the affective reactions. I have never failed to obtain a galvanic reflex to a loud sound in cases of hysterical deafness. Another example of the difficulty in drawing an absolute line between voluntary and involuntary symptoms in hysteria is furnished by the vestibular reactions.

I have been able successfully to suggest a definite vertigo to two cases of hysteria who complained of ill-defined symptoms of giddiness. In both these cases when they were asked to perform the pointing test with their eyes shut they invariably showed a deviation corresponding to the direction of the suggested vertigo. Thus in the absence of the start reaction we have an involuntary mechanism definitely suppressed and in the vertigo reaction we have it appropriately altered, when a strict interpretation of hysteria in the terms of Babinski's definition would require them to remain unaffected. What may be the nature of the pathological changes responsible for this hypoexcitability of the mechanism of affection in hysteria it is impossible at present to specify. That the organic change exists prior to the development of the more obvious symptoms may be inferred from a study of the previous history of such cases. The diagram (Fig. 5) is constructed from the statistics of Kraepelin of the age-incidence of hysteria based on 430 cases. Although the years immediately succeeding puberty are those most affected by "Sturm und Drang" it would hardly be expected that the fall in the curve would be so steep were it not that a definite amelioration of the organic response rather than a disappearance of environmental stress is the responsible factor.

FIG. 5.



Kraepelin's curve of age-incidence in hysteria.

CONCLUSION.

At the risk of wearying by reiteration, I will again call your attention to the absence of any proof that the early experiences of the hysteric differ from those of the majority of mankind and to the fact that they therefore cannot be held to play any considerable part as predisposing factors. Of the disturbances of mechanism responsible for the psychoses I do not propose to speak. We have already seen how the observations of Mott and his pupils may be considered to have definitely settled the question of the organic origin of dementia præcox. The profound metabolic disturbances in manic depressive insanity, though still awaiting investigation, are indicative of a similar organic basis. Through the kindness of Dr. Mapother I was able to satisfy myself that the seemingly violent emotional activity of mania is unaccompanied by objective signs of hyperexcitability of the mechanism of affection. Were but a tithe of the attention at present devoted to the classification and tracing of psychogenic disturbances in the insane given to an objective study of their nervous mechanism by physiological methods, we should probably before long have remedied the deplorable condition of the pathology of insanity. Unhappily asylum authorities have not yet recognised the necessity for observers skilled in physiological methods.

In concluding these lectures I must acknowledge with the profoundest sense of obligation the kindness and encouragement in their preparation that I have received from Sir Frederick Mott, in whose laboratory at the Maudsley Hospital the experimental work connected with them has been performed.

THE TREATMENT OF THE IMPERFECTLY DESCENDED TESTICLE.*

BY CHARLES A. PANNETT, B.Sc., M.D. LOND., F.R.C.S. ENG.,

ASSISTANT DIRECTOR, SURGICAL UNIT AND OUT-PATIENT SURGEON (ADDITIONAL), ST. MARY'S HOSPITAL.

HOWEVER we look at the problem of the imperfectly descended testicle it must be conceded that our present methods of treatment are unsatisfactory. Our knowledge of the condition, so far as it goes, points to the lack of some hormone whose exact nature and point of origin have hitherto eluded scientific research. The future of treatment will, undoubtedly, be in the provision of the missing chemical stimulus, but until we are in a position to do this we must perforce employ methods which fall short of this ideal in their intent, and anything which will further or improve the technique of these measures must not be neglected. From this standpoint it is of first importance to recognise two classes of cases of deranged testicular descent. In the first the testicle starts along its normal path and then becomes arrested before it has emerged from the inguinal canal—that is, an inhibition occurs of a process begun in normal fashion. In the second the testicle emerges from the external abdominal ring, but instead of passing into the scrotum it is diverted to some abnormal situation (the ectopic testicle).

When the organ is simply arrested in its normal path to the scrotum experience has shown that average activity cannot be expected from it, but an ectopic testicle may histologically and functionally be a normal organ. As Thomson Walker says,[1] "the imperfectly descended testicle may never produce spermatozoa, and when it does, this activity may but last for one or two years and then disappear. But all observers have agreed that such testicles produce the internal secretion necessary for the development of the male characters."

In treating this condition our choice lies between two procedures, orchidopexy and orchidocœlioplasty.

Orchidopexy.

Many operations have been designed for the placing of the testis into the empty scrotum. This is the procedure of choice when it is possible without prejudicing the subsequent development of the organ. The obstruction to the easy retention of the testis in the scrotum is the shortness of the spermatic vessels. The experience of all surgeons is that the tendency to retract after operation is very great, but this does not apply to the ectopic testicle. Published statistics have not distinguished between the ectopic and the incompletely descended testicle, and they point to better results than can be expected, and indeed occur, if only the cases of arrested descent be considered. In this connexion it is to be remembered that an inguinal testicle is frequently an ectopic organ. It is very common to find that the testicle has emerged from the external abdominal ring and then turned upwards and outwards towards the anterior superior spine of the ilium coming to lie upon the surface of the external oblique. When this has happened the spermatic vessels are often of almost normal length and the testicle can be placed in the scrotum without them being an obstruction to this manœuvre. The same applies to the perineal testicle. It is not always the case in crural ectopia. Should the testicle emerge from the external ring and then be dragged into the thigh, as described by Eccles, the spermatic vessels would probably be of sufficient length, but I have not operated upon such a case. In a true crural ectopia I opened the inguinal canal, dragged the hernial sac and testis up along the crural canal (as in the inguinal operation for femoral hernia), but glass stomach. A partial gastrectomy is preferable. The operation performed was the usual posterior, except in two cases, where, owing to the fixation of the stomach to its bed, a modified anterior operation was done, the jejunum being pulled through a hole in the transverse mesocolon and great omentum and anastomosed to the lower border of the anterior wall of the stomach. These cases did exceptionally well. In most cases the pylorus was ligatured and in two cases actually divided. The additional time and risk attached to this procedure is perhaps not justified, although the immediate and later results of this operation were exceedingly satisfactory; three cases had undergone an operation for perforation before, and their ulcers had remained active and necessitated further treatment. In all cases the appendix when present was removed at the same time.

---

* A paper read before the Royal Society of Medicine on June 1st, 1921.

[1] Text book of Genito-urinary Surgery, 1911.

(c) It has already been stated that gastro-enterostomy for dilated stomach not due to organic obstruction is a bad operation. The writer performed it in one early case of general visceroptosis with marked gastric symptoms, and the patient died of high intestinal obstruction. In such cases the atonic musculature renders gastro-enterostomy hazardous, but even if a vicious circle is avoided no benefit is likely to be derived from the operation.

Excision of Simple Ulcer.

A few years ago this was much in vogue, but now is less frequently practised. By excision is here meant wedge-shaped resection (nine cases), sleeve resection (one case), local excision—i e., artificial perforation and closure (three cases), transgastric excision (one case). One case died of pulmonary embolism 24 hours after operation. Excision appeared at one time to be an attractive method of removing the disease completely without sacrificing too much of the stomach. Of late it has been performed less frequently. Its final results are disappointing. Five cases report themselves as quite well, one was quite well when last seen one year and eight months after operation, four are not happy with their digestion, and four have been lost sight of. The results of excision cannot be compared with those of partial gastrectomy. It has the following disadvantages: It has a higher mortality. It is often most difficult of performance. It is apt to leave a deformed stomach. On two occasions pylorectomy has been performed for hour-glass stomach resulting from a previous excision. This series of cases shows that a partial gastrectomy can be performed with less risk and greater permanent advantage to the patient.

Partial Gastrectomy for Simple Conditions.

Partial gastrectomy has been performed on 25 occasions with one death: (*a*) for simple ulcer, (*b*) for hypertrophied and dilated stomach, and (*c*) for myoma.

(*a*) *For Gastric Ulcer.*—It is undoubtedly the most satisfactory method of dealing with ulcers of the lesser curve and the pyloric half of the stomach. The immediate results are excellent. The only fatal case was that of a man of 47 with a very large ulcer and in very poor condition. He died suddenly of syncope 12 hours after operation. Post mortem: No other cause of death could be found. The post-operative course is exceptionally easy. Patients suffer from no more shock and much less vomiting than after gastro-enterostomy. The final results are excellent. Of the 21 cases of ulcer successfully submitted to gastrectomy 15 have been examined recently and are in perfect health. Six are known to have been cured of their digestive complaints at periods of from one to two and a half years after operation. I know of no more grateful class of patient than those who have had gastrectomy performed for ulcer. This, after all, is the best test of the operation, but it has other features to commend it. It removes an ulcer especially prone to malignant change. In two cases where ulcers were removed in the belief that they were simple routine pathological examination showed early carcinoma beginning in the edge. It is more certain to cure symptoms than gastro-enterostomy alone. Two cases had had gastro-enterostomy previously performed elsewhere for ulcer of the lesser curve and pylorus, and their symptoms had persisted. At further operation the ulcers were found still active and partial gastrectomy was performed. They have been in perfect health during the three and a half and four and a half years which have now elapsed since operation.

(*b*) *For Hour-glass Stomach.*—Partial gastrectomy is the ideal method of treatment for hour-glass stomach. It is more usual to perform gastro-enterostomy to the proximal or distal pouch, or both. Symptoms may be relieved, but the final result is ugly in the surgical sense, and a deformed stomach is left with ulcer or scar untreated. The best results, in the writer's experience, are obtained by complete removal of the ulcer or scar and distal pouch and the fashioning of a new stomach out of the proximal half. This series includes cases where gastro-enterostomy and gastrectomy have been done, and the final results of gastrectomy are strikingly better.

And for Hypertrophied and Dilated Stomach.—Cases are sometimes met with when very long-standing pyloric obstruction has caused enormous hypertrophy and dilatation of the stomach. Usually the pylorus has been the site of an ulcer which has healed some years before. In two cases of this series the size of the stomach was astonishing. The stomach was a huge thick-walled bag with a greater curvature reaching to the pelvis. The pylorus was in either case quite atrophied and would just admit a quill. It was manifestly impossible to drain the stomach at its lowest point by a gastro-enterostomy, so in each case the vast excess of stomach was removed, the cut ends were closed, and gastro-enterostomy performed to the new stomach of normal size. One case is worthy of record.

J. W., aged 69, had suffered for 50 years from pain after food and vomiting. For the last 20 years he had washed out his stomach six times a week. He was becoming feeble from malnutrition and toxæmia. At operation the pylorus was almost completely stenosed, and the stomach dilated and hypertrophied to an extraordinary degree. About half the stomach, including the pylorus, was resected. The circumference of the resected part measured 12 in., 11 in. of the greater curvature being removed. There was practically no shock and the patient made a rapid convalescence. He is still in excellent health (at the age of 73) with no stomach symptoms whatever, although for some months after operation his 20 years' habit was so strongly ingrained that there was difficulty in restraining him from his daily stomach wash-out.

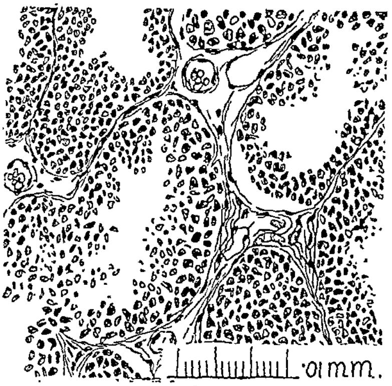
(*c*) *For Myoma of the Stomach.*—There was one case of pyloric obstruction which was found on operation to be due to a rounded tumour of the pylorus projecting into the lumen. The patient was a woman, aged 61. A partial gastrectomy was performed and has been followed by complete relief. The tumour proved to be a myoma.

The Operation.

The operation employed for partial gastrectomy for ulcer has followed largely the Billroth II. method. The vessels are first controlled, and the gastro-hepatic and gastro-colic omentum divided. The duodenum is crushed and divided and the duodenal stump inverted. Posterior gastro-enterostomy is performed—the jejunum being joined to the proximal part of the stomach. The ulcerated part of the stomach is then removed through healthy tissue and the cut end closed. The writer has tried other methods but finds this the easiest and safest; 40 to 45 minutes is the average time consumed, and drainage is usually not necessary. If in doubt as to the duodenal closure, it is wise to leave a tube in the wound for 24 hours. In two cases a duodenal fistula appeared a few days after operation. If the patient is put on an egg diet—12 to 14 eggs a day—the fistula rapidly closes. Catgut is used throughout. The chief difficulties met with during an operation are the result of dense adhesions. Adhesions of the ulcer to the pancreas are not so formidable as they

The third objection rests upon some experiments performed on dogs by Joseph Griffiths.[8] He states that following his operation the spermatogenic cells degenerated and the tubules were left with a lining of a single layer of cells elongated towards the centre. Griffiths gave no details of his actual procedure, so I have repeated the experiments in two adult and one young rabbit. In this animal the tunica vaginalis is not shut off from the peritoneal cavity, and it is easy, after a laparotomy, to drag the testicle up into the abdomen. In one animal this was done on the left side through a lateral laparotomy wound, and the thick gubernaculum cut across. Great care was taken not to injure the spermatic vessels or vas, and the gland was sutured to the abdominal wall by a stitch going through the gubernaculum. Healing occurred by first intention and there were no obvious effects produced. Four months later the animal was killed and both testicles removed for examination. The abdominal testicle was found to have shrunken in size, its weight being 1·75 g. compared with a weight of 5 g. for the opposite normal organ. Figs. 2 and 3 are drawings from sections of the abdominal and scrotal testes. In the abdominal testicle there is a complete disappearance of spermatozoa; the spermatogenic cells are degenerated and those derived from them are absent, so that there is a diminution in size of the tubules. Other cells lining the tubules are not so affected and their nuclei take on the stain in normal fashion. The interstitial tissue is much increased. There is no evidence of any vascular change. In the interstitial tissue, Leydig's cells, so obvious in the human testis, are not detectable. I regard Fig. 2 as representing the end-result on the structure of the seminal tubules, for four months in the rabbit correspond to a span of a number of years in a human life.

FIG. 3.

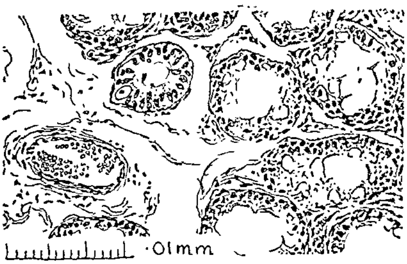


Normal rabbit's testicle.

Fig. 4 shows something of the genesis of these changes. This testicle had been replaced in the abdomen by an inguinal operation for two months only. It shows less interstitial cell proliferation and fibrosis. The most interesting features are the changes in the tubules themselves. In the tubule cavities are the evident remains of the degenerated spermatogenic cells, whilst there is a lining layer of a single row of low epithelium. Undoubtedly, the low cells elongate centripetally. Thus it will be seen that after abdominal replacement the spermatogenic cells and their derivatives degenerate, whilst certain cells lining the tubules, presumably not concerned in the spermatogenic function, remain alive. Probably these cells by their activity maintain the male characters, for Von B. Romeis[9] has pointed out that Steinach's assertion[10] that sex characters depend upon the interstitial cells of Leydig has not been confirmed by other authors, and that the function of these cells is still undetermined, whilst Sejous asserts that certain cells in the seminal tubules correspond to the suprarenal medullary cells and are part of the chromaffin system upon the integrity of which the male characters depend.

The questions may well be asked: Why do these degenerative changes occur when the testis is simply replaced in the abdominal cavity? Why has its function been so seriously deranged? Need it be an inevitable result? It was in answer to these problems that I was tempted to repeat Griffiths's experiments, which have, so far as I know, not been carried out by other observers. I approached the problem with the idea, almost amounting to conviction, that there must either be some interference with the vascular supply, or some obstruction of the vas deferens, produced by the operation. If this were so and such injury were shown to be avoidable, orchidocœlioplasty would become the operation of choice in the incompletely descended testicle. Griffiths's experiments were performed upon dogs. I selected the rabbit because in this animal the cavity of the tunica vaginalis remains connected permanently with that of the abdomen, so that peritoneal fluid bathes the testis equally when it lies in either cavity; moreover, the testicle can be pulled up into the abdomen with scarcely any disturbance of the neighbouring parts. The experiment in the rabbit would seem, therefore, to be more simple and less liable to disturbing factors than in the dog. Injury to blood-vessels or vas deferens was sedulously avoided, and microscopical sections lend no support to the view that any derangement of the blood supply occurred in the experiments. We are thus driven to furnish some other explanation of this baffling phenomenon of testicular atrophy, and I think it is to be found by a consideration of the anatomy of the testicle. This gland is unique in the relation of its secreting acini to its excretory duct. There are no comparatively straight channels running from the secreting elements to fuse obliquely with neighbouring ducts to constitute an ever enlarging tube until the main duct is reached, as, for example, in the pancreas. In the testicle, between the seminal tubes, which are themselves very tortuous, averaging 2 ft. in length, and the main excretory duct—the vas deferens—the testicular secretion has to follow a very devious course. First it passes through the convolutions of the coni vasculosi, and then along the tube of the epididymis, a minute channel 20 ft. or

FIG. 4.



Rabbit's testicle two months after orchidocœlioplasty.

gastrectomy. The smaller stomach left after removal of the greater part of the lesser curve and pylorus seems to produce no disability afterwards. The disease is removed entire through healthy limits. There is no operation which causes so little anxiety both at the time and during convalescence with so great a permanent improvement in the subsequent health of the patient. There will be certain cases—e.g., cases of low vitality demanding a quick operation where gastro-enterostomy only is advisable. The results, however, judging from these cases, will not be so good as with the more complete operation. Wedge-shaped and sleeve resections have been given up. They are more difficult of performance. The result is often unsightly and the permanent effects not so good as can be obtained by partial gastrectomy.

3. The consensus of opinion has been for some time that duodenal ulcers can be cured by the operation of gastro-enterostomy. This series of cases, short though it is, certainly bears this out. It is probable that bad results from this operation come from mistaking duodenal symptoms for duodenal ulcer, and performing gastro-enterostomy without definite pathological evidence of ulcer. In the writer's experience the classical symptoms of duodenal ulcer are not so definite as has been stated, and hunger pain, as Waugh has pointed out, is symptomatic also of other conditions.

AN EXPERIMENTAL STUDY OF PROPHYLACTIC INOCULATION IN TYPHUS FEVER.

BY PROF. S. KUSAMA, M.D.

(*From the Kitasato Institute for Infectious Diseases, Tokio.*)

OF the three successful examples of prophylactic inoculation against acute infectious disease caused by an invisible virus—viz., Jenner's vaccination against small-pox, Pasteur's preventive treatment of hydrophobia, and Koch's inoculation against rinderpest—the first two are made with a so-called fixed virus, which has been passed through the bodies of heterologous animals for many generations, its attenuation having been effected in the process, while the third is made with the bile of infected cattle. Although the nature of rinderpest vaccine is not yet clearly known, it seems highly probable that it contains the virus in a considerably attenuated state. Hitherto all investigators who have experimented in prophylactic inoculation of acute infectious diseases with accompanying exanthem have used either attenuated virus or bile of infected animals, but none save those already mentioned has yet succeeded in obtaining any efficacious result with them.

Since last spring I have been experimenting with typhus, the causative agent of which seems also to be invisible virus, and have employed the Japanese monkey (*Macacus fuscatus*) in an endeavour to find a means of prophylaxis against it. I found that, as stated by Nicoll, human convalescent serum was efficacious in preventing infection by the virus. I also found that monkeys' convalescent serum, if used in a certain dosage (e.g., more than 1 c.cm. per kilogramme of body weight of the animal), has also a preventive effect against infection by 50 times the minimal morbid dose of the virus, which fact was reported before the meeting of alumni of the Kitasato Institute for Infectious Diseases in April, 1919. Such passive immunisation may be of experimental value, but it is difficult to apply in general practice, as the serum cannot be obtained cheaply enough at the present time. I therefore attempted to discover an attenuated virus. For this purpose I treated the blood of the infected monkey either physically or chemically, or inoculated the virus into the body of various species of animals for several generations, or used virus withdrawn from the animal towards the close of the course of the disease; all trials with these materials, however, proved negative.

Observations on Results Obtained.

From my study of typhus during the past two years—in which period I have employed over 200 Japanese monkeys—the following facts have been clearly observed:—

(*a*) The incubation period differs according to (1) the site of inoculation of the virus, (2) the virulence, and (3) the quantity of virus or blood. The incubation period is shortest when the virus is inoculated into the vein, or is very strong, or given in a large quantity. By injecting the virus hypodermically, or employing a virus of weak potency or in small quantity, the incubation period is lengthened. If virus of the same potency is inoculated at the same site, the incubation period will naturally be influenced only by the quantity.

(*b*) The incubation period is indirectly proportional to the pyrexial period. If the symptoms develop after a longer period of incubation, the days of disease are fewer, and vice versa.

In the light of the above-mentioned conclusions, it may be said that under the same conditions the incubation period is lengthened or shortened according to the quantity of virus inoculated; the period may be lengthened at will by inoculation of a very small quantity of the virus. Thus we may find a dose of virus, small enough to shorten the days of disease, producing practically no symptoms, whilst at the same time giving a certain degree of active immunisation to the inoculated animal. If this idea prove true, there will be no need to attenuate the virus either by fixing or by passage through the animal body; simply by giving a very small dose a certain degree of immunisation may be bestowed on the animal. Considering this to be attainable, the next step was to find out the quantity which would bring about such theoretical results in monkeys.

Details of Experiments.

Experiment 1 (August 28th, 1919).—The strain of virus here employed was obtained from a female case, Midzuguchi, in 1918, in the Aomori Prefecture, by the author and his assistant Yanagisawa. It had passed through 32 generations at the time of experiment, the virulence being just enough to infect a Japanese monkey with an attack of 9 to 11 days pyrexial period, after 8 days' incubation, by intravenous injection of 0·5 c.cm. of the sick monkey's blood. The infected blood was first diluted with sterile sodium citrate solution (2 per cent. sodium citrate and 1 per cent. glucose in physiological saline), in order to prevent clotting, and then diluted with the saline to different concentrations, so that 1 c.cm. of each dilution corresponded to 0·1, 0·01, 0·001 c.cm. of the original blood. In all experiments here reported the same dilutions were used.

Three Japanese monkeys were treated as follows: No. 100 was given 0·1 c.cm. of guinea-pig's blood (thirty-second generation of Midzuguchi strain); No. 99 was given 0·01 c.cm. of guinea-pig's blood (thirty-second generation of Midzuguchi strain); and No. 103 was given 0·001 c.cm. of the blood of monkey No. 102 taken on the fourth day of sickness (thirty-sixth generation of Midzuguchi strain). All the injections were made intravenously. Monkey No. 100 had onset of fever after an incubation of 9 days and No. 99 after 16 days, but No. 103 had no rise of body temperature even after 25 days. Nos. 100 and 99 had pyrexial periods of 7 and 8 days respectively.

By the results thus obtained the theory has so far been proved to be true; a small quantity of the affected blood—e.g., 0·001 c.cm.—did not produce the clinical symptoms at all, while the larger the dose the longer was the pyrexial period and the shorter the incubation period. In order to see whether monkey No. 103, which had no clinical symptoms, had acquired active immunity or not, I injected hypodermically 0·5 c.cm. of the blood of monkey No. 104 (withdrawn on the fifth day of sickness produced by inoculation with Midzuguchi strain at the thirty-eighth generation). This was just 50 times as much as the minimal morbid dose. The animal had no attack of the disease, and was thus clearly proved to have acquired a certain degree of immunity from the first inoculation.

Encouraged by this favourable result I wanted to repeat the experiment, but unfortunately I could not obtain a monkey, and so the strain of virus was lost;

more so when an attempt is made to cure permanently a condition the cause of which is unknown. Numerous theories of ulceration have been advanced—oral sepsis, embolism, intestinal stasis. The modern trend is to search for some broad pathological basis. Association of symptoms and pathological findings has for some time pointed to the right iliac fossa as the starting-point of gastric and duodenal ulcers. The appendix, the terminal ileum, and the ascending colon have borne the brunt in turn. The most attractive and the most recent addition to the subject is contained in an original and very suggestive paper by G. E. Waugh in the *British Journal of Surgery*[1] on the Morbid Consequences of a Mobile Ascending Colon. Although discussion of the general part of that article is beyond the scope of this paper, yet acknowledgment must be made here of the substantial relief his work must bring to a very large body of sufferers. The patient who before would have been subjected to colectomy, ileocolostomy, or the removal of an inoffensive appendix can now be offered an operation by which he will lose nothing and may gain much. This must be said in passing. But for the moment it is only necessary to consider Waugh's theory of the formation of duodenal and gastric ulcers. He attributes the ulcer formation to the weight of a loaded and mobile colon causing destruction of tissue at the point of strain. Exact figures are not available, but it is believed that in most cases of ulcer in this series an abnormally mobile colon was present. This does not necessarily mean that ulcer is caused by the mobile colon. An abdomen in which the colon is abnormally mobile is a pathological abdomen, and as such is more prone to pathological processes than the normal type. The abnormal mobility is the predisposing cause. What is the exciting cause? Waugh's theory is a mechanical one. He believes that the pull of bands and ligaments determines the ulcer, and adduces much evidence in its favour. He has successfully treated formed ulcers of the stomach and duodenum by colopexy only. But even if it is granted for a moment that mobile colon is indirectly or directly the cause of ulcer it must be confessed that in the class of ulcer dealt with in this paper there was not the surgical courage and optimism to leave the ulcer untouched in the belief that healing would straightway follow. In two of these cases the ulcer had practically perforated; sometimes withdrawal of the stomach was sufficient to cause it to perforate. In the case of other large callous ulcers involving most of the stomach tissue death had gone so far that natural repair could not be expected. In two cases routine microscopical examination of chronic ulcer showed an early carcinoma at the base.

Problem of Dealing with Ulcers.

Even, then, if we look with favour on Waugh's theory, the problem of dealing actively with the ulcer is still before us. Some years ago the writer determined to test the various approved surgical methods of dealing with stomach disorders and to keep a close watch on his patients afterwards. All patients were subjected to a complete chemical and radiographic examination and a large amount of material was investigated. This paper is based on 100 consecutive cases. No case is included that was operated on less than 18 months ago. Cases of acute perforation and congenital pyloric stenosis of infants have been omitted. An attempt has been made to collect, by interview or by letter, reports from all cases. The result has enabled the writer to arrive at certain definite conclusions, for his own guidance, as to the operative procedures which will give the best results in different types of case. In the treatment of ulcers the extent of success is only limited anatomically. Ulcers that are entirely accessible can be cured. The inaccessible can be relieved. With tumours it is the same, early recognition in this case being the dominant factor.

The operations may be tabulated as follows (O.M.: operation mortality):—

			O.M.
1. Gastro-enterostomy for	(a) duodenal ulcer ..	21	0
	(b) gastric ulcer ..	20	1
	(c) dilated stomach ..	1	1
2. Excision of simple ulcer	.. .. ..	14	1
3. Partial gastrectomy for	simple ulcer	22	1
	hypertrophied and dilated stomach	2	0
	myoma	1	0
4. Pyloroplasty	.. ..	1	0
5. Partial gastrectomy for	carcinoma	7	1
	sarcoma	1	0
6. Inoperable carcinoma	.. ..	7	1
Gastro-enterostomy for carcinoma	.. ..	3	1

Gastro-enterostomy.

Gastro-enterostomy is a most valuable operation for diseases of the stomach, but it has been very much abused. Disappointing results in gastric surgery are attributable rather to the performance of gastro-enterostomy without adequate indication than to any other factor.

The clear indications for gastro-enterostomy are: (1) gastric stasis due to organic obstruction of the stomach; and (2) an ulcer of the stomach or duodenum which may be afforded rest and allowed to heal by a short-circuiting of the food path.

The absolute contra-indication is an atonic dilated stomach. A more debatable indication is the presence of an ulcer in such a situation in the stomach (cardiac end) that gastro-enterostomy cannot give rest to the ulcer. Neutralisation of the acid juice is given as the justification of this procedure, but in 45 per cent. of ulcers of the body of the stomach in this series examined by Dr. E. H. Shaw the acidity was normal or reduced. This theory does not appeal to me, and I have found in these cases that the further from the cardiac end and the nearer to the duodenum the ulcer was situated the better were the final results.

(*a*) *Gastro-enterostomy for Duodenal Ulcers.*—Gastro-enterostomy was performed 21 times for duodenal ulcers. There were no deaths. In accordance with the experience of others the results were very satisfactory; 15 cases are under observation at the present time, and of these 13 enjoy perfect health and have no digestive trouble whatever. One suffers from discomfort and a feeling of hyperacidity after meals, and one has vague abdominal pains, but no symptoms directly referable to the very large ulcer which was short-circuited. The six others were all in excellent health when last seen at periods varying from four months to two years after their operations. The operation performed has been the usual posterior "no loop" operation, with the stomach opening in the Mayo line. Catgut was used throughout. The pylorus was closed in most cases. The immediate results seemed to be better and the post-operative course smoother after ligature of the pylorus. The final results were not much affected.

(*b*) *Gastro-enterostomy for Gastric Ulcers.*—Twenty cases were operated upon, of which one died. The fatal case was that of a woman, aged 59, who was found at operation to have a large perforation of the pylorus which had been closed by adhesion to the gall-bladder. Gastro-enterostomy was performed and the hole closed. Unfortunately, the pylorus leaked and she died 16 days later. Post mortem extensive sloughing of the pylorus and duodenum was found. Of the 19 cases remaining 11 have been seen or questioned at the present date and 13 are in good health. One suffers from "occasional indigestion." Of the remaining five, two appeared to gain little relief from the operation, one has been lost sight of, and one, a case of double gastro-enterostomy for a severe hour-glass stomach, has never been quite satisfactory. Five ulcers were of the cardiac, 15 of the pyloric half of the stomach. The poor results were cases of ulceration near the cardiac end of the stomach. The writer has for some time ceased to perform this operation for ulcers in this location in the absence of gastric stasis. Nor does he employ it now for hour-must be settled by future research. The purpose of the present paper is only to draw the attention of investigators to the fact that the use of a minute quantity of typhus virus, not attenuated by a special method, can harmlessly confer upon an animal a prophylactic power against the virus. It is sincerely hoped that this discovery may throw some light on the prevention of those diseases which have invisible viruses as their agency.

SOME OBSERVATIONS ON BASAL METABOLISM IN MENSTRUATION.

BY MARION O. P. WILTSHIRE, B.Sc.

(From the Physiology Laboratory, London (R.F.H.) School of Medicine for Women.)

THE theory that the life processes of women undergo a periodic variation correlated with menstruation has been suggested by many writers and was emphasised as long ago as 1876 by Jacobi, and again by Goodman in 1878. Since then the effect of menstruation on the life processes of women has been studied in various ways. The lines along which these investigations have proceeded include observations on the temperature, pulse-rate, blood pressure, the metabolism of nitrogen, phosphorus, and calcium, the excretion of creatine, and the CO_2 output and O_2 consumption. The results recorded are extremely conflicting, but the later, and probably more accurate, observations all point to the fact that, with the possible exception of temperature and perhaps also of pulse-rate, there is no periodic variation in any of these values. In the case of temperature most workers agree that there are slight but definite periodic changes correlated with menstruation.

In view of these conflicting results it was decided to undertake yet another series of experiments comparing the physiological processes in the menstrual and inter-menstrual periods. The points chosen for determination were: (1) the basal metabolic rate of normal women during menstruation and between menstrual periods; and also at these times (2) the cost to the organism of a certain definite piece of work, and (3) the rate of recovery from that work.

(1) Observations were made on five subjects, the basal metabolism being determined, as far as possible, each day during the menstrual periods and three or four times between these periods. In three cases the subjects came to the laboratory about 8 A.M., in the post-absorptive condition, and lay down for half an hour before the experiment began. A five-minute sample of expired air was collected in a bag, measured, and analysed by means of the Brodie gas analysis apparatus. Of the other two subjects more numerous observations were made, and the samples collected while they were still in bed. The height and weight of each subject were determined, and the surface area read off from a Du Bois height-weight chart. From these data, the O_2 consumption per minute per sq. m. of body surface was calculated, and Table I. gives the average results for each subject for the different phases of the monthly cycle.

TABLE I.

Subject.	No. of periods covered by observations.	Total No. of observations.	C.cm. O_2 consumed per sq.m. per min.			
			Pre-menst.	Menst.	Post-menst.	Inter-menst.
I.	5	39	139	139	145	146
II.	4	25	144	143	141	142
III.	4	29	140	140	132	139
IV.	6	58	116	109	109	116
V.	2	33	111	114	117	116

When the results are expressed in this way the respiratory quotient (R.Q.) is not taken into consideration. As this was found to be variable and not constant, as is frequently assumed, the calorie value per sq. m. per hour was calculated, taking the R.Q. into account. These results are given in Table II.

TABLE II.

Subject.	Caloric value per sq.m. per hour.			
	Pre-menst.	Menst.	Post-menst.	Inter-menst.
I.	40·7	40·2	40·4	40·9
II.	40·4	40·4	40·5	39·8
III.	40·2	40·8	38·9	40·3
IV.	33·5	31·3	31·5	33·1
V.	32·2	32·5	32·8	32·2

It will be noticed that the inter-menstrual values vary considerably in the different subjects, although the mean value, 37·2, agrees with that given by Benedict as an average value for women. The variations during the different phases of the sexual cycle are so small that they cannot be regarded as showing any marked effect due to menstruation; the fluctuations which normally occur are often greater than these variations. This conclusion agrees with that recently expressed by Blunt and Dye, but it is not in accordance with the view put forward by Snell, Ford, and Rowntree. These observers, in a preliminary communication which appeared last year, expressed the belief that menstruation "does affect the basal metabolic rate in women at times in health and in disease."

(2) and (3) Although the results obtained show that the basal metabolism is not appreciably affected by menstruation, it seemed possible that the cost of work to the organism during the menstrual period might differ from that during the inter-menstrual period. Consequently a few determinations have been made to test this possiblity, and although these experiments are not yet completed, the method and an example of the results obtained are included here. A certain definite piece of work was performed on days during the menstrual period and again during the inter-menstrual period. The amount of exercise is very much less than that performed in the experiments of Krogh and Lindhard, and of Douglas, Campbell, and Hobson, on the subject of respiratory changes during work and rest. This small amount of exercise was selected as it was found that the subject could undertake it without any real physical fatigue; with greater amounts this was not so. The work consisted in stepping up and down on a low stool in time with a metronome; the exercise lasted for three minutes, 36 steps per minute were taken, the stool being 6½ in. high. The basal metabolism was first determined in the usual manner, and then, after the subject had been standing for about five minutes, a half-minute sample of expired air was taken before exercise began. During the exercise half-minute samples of expired air were collected during the first half of each minute. After the cessation of exercise the subject remained standing and half-minute samples of expired air were collected during the first three minutes, and then during the fifth, seventh, ninth, and eleventh minutes, by which time it was found that the metabolism was restored to normal. The O_2 intake and CO_2 output for each of the half-minutes were determined and the results are given in the graphs, Fig. I. being a result obtained during the inter-menstrual period, and Fig. II. during the menstrual period. These indicate that the cost of work and the rate of recovery from work are the same during the menstrual and inter-menstrual periods. In both cases there is a sharp rise in the CO_2 output and O_2 intake during exercise, followed by a gradual return to the resting value when work ceases. The greatest drop occurs during the first two minutes of rest, the fall after this being much more gradual. The variations in the R.Q. are interesting. Whilst the work is being done the R.Q. falls at first, usually being lowest during the second minute of work with a tendency to recover during the third minute of work. After cessation of work the R.Q. rises very rapidly,

may at first appear. As a rule, with cautious persistence the stomach can be dissected off the pancreas and a portion of the pancreas can be sacrificed if necessary. Adhesions to the transverse mesocolon, especially when the mid-colic artery is involved, present greater difficulty. The vessels may be so endangered that the possibility of having to perform colectomy as well makes the risk greater than the condition warrants and radical treatment of the ulcer should not be attempted.

After-treatment.—Nothing is allowed by the mouth for 36 hours; 10 per cent. glucose and saline is given rectally. Morphia is given without stint for the first 24 hours; after 36 hours fluids are allowed until the morning of the fourth day, when a purge is given and the diet is then rapidly increased. Chicken is usually taken on the tenth day and the patient is allowed up on the fourteenth day and home on the seventeenth day. Convalescence is, as a rule, surprisingly easy. In fact, when once the operation is concluded there is even less cause for anxiety than after gastro-enterostomy. Vomiting is uncommon. Nor is there any need to diet the patient after recovering from the operation. There have been no cases of gastro-jejunal or jejunal ulcers following gastro-enterostomy or gastrectomy.

Pyloroplasty.—A young woman, aged 22, presented the symptoms and signs of pyloric obstruction. At operation a spastic condition of the pylorus was found. The pyloric ring was so rigid and thick and resembled so closely the hypertrophic pylorus of infants that it was decided to try Ramstedt's operation. This was done and has proved quite successful. She writes two and a half years after operation: "I have not had a return of the complaint and my operation has been quite successful." The cause of this curious condition of the pylorus was not determined. There had been no history of stenosis in infancy. There was no sign of ulceration or inflammation. The hypertrophy of the circular fibres was most marked. The rest of the abdomen was normal.

Operations for Malignant Disease.

Sarcoma.—There was one case of sarcoma in this series. It has already been fully reported.[2] Gastrectomy was performed in 1916 and the patient has recently reported (December, 1920) that he is still in perfect health, hard at work.

Carcinoma.—In 17 cases of carcinoma of the stomach seven were found on operation to be beyond surgical help by reason of extension and dissemination. In three the growth was not removable, but gastro-enterostomy gave relief for a period; seven cases were subjected to gastrectomy; one case died as the result of operation. It was that of a man of 58 with carcinoma of the body of the stomach involving the colon. The growth was removed together with part of the transverse colon. He was making an excellent recovery, when 14 days after operation a small perforation occurred at the colon line of suture and he died from shock and toxæmia within a few hours. The other cases did immediately well, but the late results are very disappointing. One, a girl of 22, died of widespread dissemination nine months after operation. Another died of local recurrence one and a half years later. Another died of local recurrence three years later. One died of pneumococcal meningitis four months after operation, and at the autopsy the abdominal condition was thoroughly investigated and no sign of disease could be found. On the face of it the results of gastrectomy for malignant disease appear disappointing, but these cases were all rather advanced and had been treated medically for some considerable time. It is every surgeon's lament that so many cases of cancer of the stomach are not suspected or diagnosed until the disease is too widespread for hope of cure. Earlier recourse to surgery in intractable stomach complaints and the more radical treatment of ulcer by gastrectomy whenever possible should improve the outlook.

Conclusions.

In the operative treatment of ulcers of the stomach and duodenum it is of paramount importance to maintain a breadth of view and to consider each ulcer on its merits. The surgeon who at once associates every ulcer with gastro-enterostomy or with excision, as the case may be, will be disappointed in his results. It must be remembered that the causation of ulcer is unknown, or at least not proved. Even if we believe we know the primary cause of which ulcers are but a secondary manifestation, yet, however desirable it is to find the cause and relieve it, the ulcer itself is fraught with such possibilities of disaster that immediate and direct treatment of the ulcer is generally desirable. Nevertheless, granted that the ulcer requires direct surgical treatment, it is our duty to explore the whole of the abdominal cavity before embarking on any set procedure. In every case of this series a complete examination of the abdominal cavity was made. The appendix was removed when present as a general precaution. As a rule it looked innocuous. Anchoring of the terminal ileum (Lane's kink) was found on a few occasions and freed. Abnormal mobility of the colon was a frequent concomitant and in recent cases (too recent for inclusion in this series) has been treated by Waugh's method. In three cases cholecystectomy for gall-stones was performed at the same time.

After the preliminary examination the exact presence and situation of the ulcer is determined. The ulcer must be established beyond doubt. If necessary, the stomach must be opened and the mucous membrane inspected from within. It is easy to be misled by a thickening of the lymphatics along the ulcer course, or on the pylorus, or by thickening of the peritoneum, into the error of believing an ulcer to be present when none is. It is, no doubt, easy when the patient or the audience are expecting the performance of a gastro-enterostomy, to conclude that a few adhesions and slight thickening of the duodenum represent an ulcer. This is the class of operation which has brought discredit on gastro-enterostomy.

If an ulcer is present it can usually be classified into one of three groups: 1. Ulcers situated, usually on the anterior surface of the stomach, sometimes on the posterior, proximal to a line drawn vertically downwards from the beginning of the lesser curve. 2. Ulcers situated between this line and the pyloric vein—usually on the lesser curve—sometimes on the posterior surface of the stomach, more rarely anteriorly. 3. Ulcers beyond the pyloric vein, most frequently at the beginning of the second part of the duodenum.

1. Ulcers of the first group are the least satisfactory to treat, and fortunately, are the least common. They are difficult by reason of their comparative inaccessibility. The best available treatment is local excision, which may be done with a knife or by Balfour's method with the cautery. Posterior ulcers are difficult. Access must be obtained by free division of the hepatic or colic omentum if necessary, or by a transgastric operation. Gastro-enterostomy is not carried out unless definite gastric stasis has been demonstrated before. Any associated condition, mobile colon, appendicitis, ileal kink, is appropriately dealt with at the same time. Until the cause of ulcer is definitely established the treatment of ulcers in this situation cannot be quite satisfactory. All that this treatment amounts to is artificial perforation and closure, and it is known that subsequent perforations are not uncommon. One of this series had previously perforated twice and at the third operation an ulcer was found about to perforate again. Four cases had previously perforated and were operated on for recurrence of gastric symptoms. It is true they were all in the neighbourhood of the pylorus, which is, perhaps fortunately, peculiarly the ulcer zone.

2. Ulcers of the lesser curve and pyloric part of the stomach are very amenable to surgical treatment. The ideal method for ulcers in this situation is a partial

---

[2] Brit. Jour. of Surg., 1916-17, iv., 301.

involving no special apparatus or equipment were quite adequate, and in particular he instanced the use of warm water.

Mr. D. McCrae Aitken (London) was in agreement with the previous speakers as to the fundamental efficacy of complete rest in the early stages, and as to the necessity for the avoidance of physio-therapeutic manœuvres. He described in detail the correct postures to be adopted in the case of the upper and lower limb, and laid special emphasis on the prevention of the common distortions of the lower limb—viz., flexion of the hip and knee.

Mr. W. R. Bristow (London) outlined the rôle of electro-therapy in the early nutritional treatment after the acute stage had passed. At first the interrupted galvanic stimulation was to be used, and this should always be applied to each individual muscle. Later, in recovering muscle, the interrupted faradic current should be utilised as soon as an effective response was elicited, but it was important to realise that a faradic response in a muscle did not mean that full function would necessarily return. During the application of all forms of electrical stimulation the appropriate splints were to be retained in position. He pleaded for the rational use of electro-therapy in this and similar conditions, and for its application to be taught more efficiently in the medical schools.

Dr. F. H. Humphris (London) dealt with the early treatment of acute poliomyelitis from the standpoint of the pure electro-therapist, and claimed that paralysis could be prevented or even cured by the early application of the various forms of electrical treatment. He considered that the whole theory of treatment by rest was open to doubt. Electrical treatment should be instituted in these patients on the first day of the illness, and its site of application should be the spine. In the later stages, of all forms of electro-therapy the static current was perhaps the most valuable.

Prof. H. Brooker Mills (Philadelphia) gave a graphic description of the vast epidemic of poliomyelitis which ravaged the North American Continent in 1916. From the aspect of preventive medicine he considered that the isolation of contact cases, and the local cleansing of the mouth and throat in infected individuals, were two measures of the greatest importance.

Mr. L. A. Parry (Hove) questioned the suitability of the plaster-of-Paris "bed" advocated by Mr. Elmslie for use in ordinary hands, on the grounds of the difficulty of its construction. He also made an appeal for the invention of more suitable types of walking instruments than those generally in use.

Mr. Harry Platt (Manchester) deplored the propagation of such teaching as that advocated in the use of electro-therapy in the acute stages of anterior poliomyelitis. He considered that the discussion had already shown unanimity on the question of the physiological correctness of complete rest both for the inflamed spinal cells and for the locomotor system in general. In the reconstructive treatment of the later stages, the difficulties encountered made one realise the vital importance of the prevention of deformity. The common flexor contracture of the hips, which in many cases prevented the child from being made to walk, could be prevented if the position adopted in the early fixation stage included fixation of the hips in hyperextension.

Dr. W. Mitchell Smith (Stoke-on-Trent) quoted an interesting experience of an epidemic of the poliomyelitis type in pigs. He referred also to the difficulties of preventing the flexion deformity of the hips and the tilting and rotation of the pelvis.

The President mentioned that he had often noticed that a large number of children affected with poliomyelitis had brown eyes.

Dr. Buzzard, in reply, reaffirmed the correctness of complete rest in the early treatment. He stated that he had listened to a lurid description of a child acutely ill, burning with fever, and with rapidly extending paralysis, being subjected to the application of a high frequency electrical current. If this was to be the future treatment of acute poliomyelitis in the early stages, then he could only hope that clinicians would never acquire the power of early diagnosis.

Arthrogenic Contractures.

Dr. Murk Jansen (Leiden) gave in brief an exposition of his well-known views on the rôle played by muscles which act on more than one joint in the production of contractures during the course of or following arthritis. The muscles of the polyarticular class always tended to dominate the monoarticular muscles which showed early fatigue. The common deformities at the hip- and knee-joints were explained by the adoption of this thesis.

Birth Paralysis.

Mr. Platt, in a short communication on birth paralysis (obstetrical paralysis, Erb's paralysis), considered briefly the modern conception regarding the pathogenesis of this disability in view of recent controversial opinions. The position now might be summarised as follows: (1) the clinical, experimental, and operative evidence was all in favour of the view that in the majority of cases there was a supraclavicular lesion of the brachial plexus; (2) there was a certain amount of evidence in favour of the view that a primary injury of the shoulder-joint capsule with secondary involvement of certain terminal branches of the brachial plexus might occasionally be met with; in this small proportion of cases all the clinical features of birth palsy might be present. From a practical standpoint it should be realised more universally that in the majority of patients spontaneous recovery of the paralytic phenomena occurred, and that operative exploration of the plexus was rarely needed. But this tendency towards natural recovery was in itself by no means always a beneficent factor, as it often determined a policy of inattention to the important postural treatment of the limb. Recovery of the spontaneous type was almost always associated with the development of a fixed internal twist of the whole arm, best marked at the shoulder-joint where the contracture was rendered more conspicuous by the accompanying posterior subluxation of the head of the humerus. In the older child the resulting disability was usually considerable and the deformity and general under-development of the limb became more and more unsightly as the years went on. As illustrating the frequency of this type of contracture might be quoted the figures of Fairbank (42 out of 60 cases) and in the writer's series 28 out of 34 cases. The contracture and subluxation could be prevented by early correct postural treatment, and in this connexion the common teaching—viz., of bandaging the arm to the side—was to be condemned whole-heartedly.

The treatment of birth paralysis could be considered under three headings: (1) early postural treatment; (2) the question of the indications for the operative exploration of the injured plexus; and (3) the treatment of the contractures in cases where the paralysis had undergone recovery. (1) At the earliest possible moment the limply hanging arm should be fixed on a splint in the position of abduction and external rotation at the shoulder, the elbow flexed, and the forearm supinated, and if necessary, the wrist in dorsiflexion. With the limb maintained the whole time in this position gentle passive stretching should be carried out daily in the region of the shoulder to prevent the occurrence of the internal rotation contracture. Later on muscle re-education, as far as is feasible in a young infant, was to be instituted. The posture was to be continued until the child developed the full power of active external rotation and abduction at the shoulder. Under such measures recovery was almost invariably seen to follow, and in the end there would be the absence of any contracture. (2) In the few cases where the paralysis was persistent after nine months of appropriate treatment, exploration of the plexus was to be considered, provided the clinical syndrome was not indicative of a lesion situated close to the spinal cord. (3) The shoulder-joint contracture could generally be overcome by manipulation under the experiments were thus discontinued at that time. In May, 1920, I visited Korea and Manchuria with one of my colleagues, Kobayashi, to study typhus, which prevails there, and at Shunsen, Kogendo, in Korea, we obtained a strain of virus from a boy of 17, which we called "Korean strain"; another strain was obtained at Kuroishi town in the Aomori Prefecture, from a female aged 43, and was called the "Kuroishi strain."

Experiment 2.—In this experiment my object was to repeat my first experiment with fresh virus, to see whether or not some different result might be obtained; the virus employed in my first experiment had passed through monkeys' bodies for many generations, and I thought some change of virulence might have occurred. In the second experiment, therefore, the virus was passed only once through the monkey's body before use.

The first series of inoculations were of the Kuroishi strain (one generation), consisting of the infected blood of monkey No. 107, given intravenously as follows: to No. 109, 0·001 c.cm. of blood; to No. 120, 0·0001 c.cm. of blood. Neither developed any symptoms; and then 0·5 c.cm. was injected of the blood of monkey No. 97 (inoculated with the third generation of Korean strain, the blood being withdrawn on the fourth day of illness); this dosage, five times the minimal morbid dose, was given hypodermically to No. 109 and intravenously to No. 120 on the twenty-second day from the initial injection. The monkeys were then continuously observed for 40 days, during which time neither of them contracted the disease.

It may thus be seen that such small quantities as 1/100th and 1/1000th of the minimal morbid dose, given either hypodermically or intravenously, will confer upon the injected animal an active immunity against five times the minimal morbid dose.

Experiment 3.—In this experiment I endeavoured to find the minimal prophylactic dose and minimal morbid dose when virus was given hypodermically. Six monkeys were employed, being given monkey's blood infected by the Korean strain, as follows:—

Monkey.	Dosage in c.cm.	Monkey.	Dosage in c.cm.
No. 141	0·1	No. 136	0·0001
No. 140	0·01	No. 135	0·00001
No. 139	0·001	No. 134	0·000001

No. 141, given 0·1 c.cm. of infected blood under the skin, had the onset of symptoms after 15 days, and six days of pyrexial period. None of the other experimental animals, which were given 0·01 c.cm. or less, had clinical symptoms. The minimal morbid dose, therefore, may be considered to be 0·1 c.cm. of the blood. The five monkeys which had been free from clinical symptoms were each given hypodermically 0·5 c.cm. of the blood of the infected monkey No. 138 (taken on the second day of the pyrexia), and the minimal prophylactic doses necessary were observed. As control animal, untreated monkey No. 144 was also given 0·5 c.cm. of the infected blood. The control animal, No. 144, had a pyrexial attack on the eighth day from inoculation, the pyrexia subsiding on the twenty-third day, while the experimental monkeys, Nos. 110 and 135, had pyrexia after an incubation period of 15 days and fever lasting for six days, with symptoms far less severe than those of the control.

The above-mentioned experiment proved that as the minimal morbid dose is 0·1 c.cm. of the blood by subcutaneous injection, 1/100,000th of the minimal morbid dose protects the animal against five times as much as the minimal morbid dose of the virus. It is also interesting to notice that the virus above a certain dosage gives the animal practically the same degree of immunisation, irrespective of the doses actually injected.

Experiment 4.—This experiment was done to determine the presence or absence of virus in the blood of the animals which had received either the prophylactic injection or the proof injection. In results hitherto obtained, the blood of animals in which experimental typhus had been produced always contained more or less of the virus throughout the course of the experiments. The virus was clearly demonstrable in the blood on the day before the febrile attack, and also throughout its duration. It has been, however, impossible to demonstrate its presence in the animal's blood during the incubation period, for even an injection of so much as 1·0 c.cm. of blood taken during the incubation period produced no symptoms in the second animal. This fact suggested the impossibility of tracing the virus in the blood of monkeys which had received a small quantity of virus for prophylactic purposes. I have, however, taken 1·0 c.cm. of blood from each of the 11 monkeys employed in the experiments, mixed the samples, and injected the entire mixture into another monkey; this animal showed no symptoms. Although this is not a conclusive proof of the absence of virus in the blood of the injected animals, it might be affirmed that in the bodies of injected animals the virus does not increase sufficiently to be demonstrable by an animal experiment.

Summary.

The results thus far obtained may be summarised as follows: None of the 12 monkeys which received injections, either hypodermic or intravenous, of one-tenth or less of the minimal morbid dose of virus had a febrile attack. This fact is very important, for in my last attempt the virus was injected without attenuation of its virulence by passage through animal bodies or by any other known methods. The degree of immunity thus obtained was not the same as in the first experiment, when the hypodermic prophylactic injection protected the animals against 50 times the minimal morbid dose; in the second experiment, in which the prophylactic injection was made both hypodermically and intravenously, the animals were protected against five times the minimal morbid dose; and in the third experiment the hypodermic prophylactic injection protected the animals against five times the minimal morbid dose. According to my experiments, the virulence of the experimentally infected monkeys' blood was greatest on the first and second days of the symptomatological attack and gradually decreased in the course of the disease until at the end of the pyrexial period it had lost a large percentage of its maximum virulence. As regards the site of injection, the intravenous injection produced a severer attack of the illness than the hypodermic; it was therefore natural that the results of immunisation of experimental animals had been so discrepant. And it may be concluded that the immunisation which can be conferred upon the animal is just great enough to protect against five times the minimal morbid dose of highly virulent virus.

The fact that the same degree of immunisation was possibly obtained by the use of very different doses (e.g., 1/10 to 1/100,000th of the minimal morbid dose) can be explained as follows: The virus that has been introduced into an animal's body may enter the general circulation to a certain degree in spite of the animal's individual protective power or resistance, acting at the same time as the antigen; thus it stimulates the formation of antibodies in the animal, but the antibodies then serve to oppose the general circulation of the virus in conformity with the individual resistance. And if all the virus is thus destroyed before it circulates sufficiently to cause the onset of symptoms, a certain degree of immunity is bestowed on the injected animal. If this assumption be true, a general circulation of virus should occur before a certain degree of immunisation is obtained, when a very small quantity of virus has been injected. If the general circulation of the virus should be so rapid that the virus approaches the minimal morbid dose, the prophylactic inoculation with the virus itself would seem highly dangerous. But with the typhus virus, as stated above, no pyrexia occurred among the monkeys after the prophylactic injection. From this fact the growth of the virus in injected animals does not appear to be rapid.

The results thus obtained would be more interesting if the experiments could be applied to the human body. The practical application must, however, be postponed until the virulence of the prevailing virus, the individual differences in susceptibility, and degree of immunisation are fully established. The three strains that I have employed—i.e., the Midzuguchi, Korean, and Kuroishi strains, were nearly equal in virulence as regards the monkeys, but no one can tell if the same holds true for men. The question of the susceptibility of man against typhus virus forms a problem difficult to solve, but there is no doubt that man has a much higher susceptibility than the monkey. The difficulty may be regulated by the use of a more diluted virus, but the immunisation thus obtained might not then be strong enough to protect the injected person against infection. These problems preserve and restore the part affected. In this treatment great attention to detail was necessary.

The various forms of such treatment were: 1. Climatic—country and marine treatment, alternated if possible. 2. Diet, hygiene, &c. 3. Local treatment—rest generally, and immobilisation of the part. In the subacute or chronic stage the patient was got up with a suitable appliance. In convalescence a retention apparatus was used. 4. Abscesses—rarely opened. Invariably aspirate with due precautions. Surgery was now confined to a very limited sphere—e.g., cases of profuse suppuration, or the removal of septic focus. 5. Adjuvant measures: (*a*) heliotherapy was very valuable, accelerating the cure, though there were patients who could not stand it; (*b*) sea-bathing; (*c*) X rays; (*d*) vaccines—were limited in their usefulness, but of value where there were infected sinuses; (*e*) certain forms of chemotherapy.

The speaker then showed a series of slides descriptive of the methods in use at Alton and Hayling Island, and of typical cases. He pointed out that interesting results were being obtained from an investigation at present being carried out on the effects of heliotherapy and sea-bathing on the metabolism of these patients. In the diagnosis, one had to be on the look out for syphilitic arthritis, osteo-myelitis, and pseudocoxalgia. He emphasised that the most dangerous form of the disease was when it occurred in the flat bones of the skull, and that this was a condition where operation should be done at the earliest moment in order to prevent dissemination.

Mr. **John Fraser** (Edinburgh) showed slides describing a certain type of diaphysitis which he considers to be a mixture of syphilis and tubercle in bone. He agreed in principle with Sir Henry Gauvain, but regretted that facilities for such treatment were not generally available in Scotland; hence early operation was more often necessary. He also approved strongly of heliotherapy and a certain form of tuberculin treatment.

Dr. **W. Camac Wilkinson** (London) emphasised the importance of early diagnosis by the practitioner, and indicated methods by which one can intervene long before the tragic results have developed. He held that bone tuberculosis was associated with the human type of bacillus, and therefore the first line of defence was the family. Bone tuberculosis was never the primary lesion, which was most commonly in the lungs or bronchial glands: (1) defence in the family must be strenuous—the carrier must be instructed and treated, and if necessary segregated; (2) defence in the bronchial glands—tubercle in these glands cannot be identified early, all tests fail except tuberculin; (3) defence in the bones—obtained by the use of tuberculin combined with treatment. He concluded (1) that tuberculin as a diagnostic is safe and trustworthy, and (2) that tuberculin as a remedy in proved ways is better than any other method, and indeed than all other methods.

Mr. **F. C. Pybus** (Newcastle) deplored the lack of local facilities. His treatment therefore was based on the means at his disposal—i.e., the out-patient department. He agreed that Alton conditions are the best form of treatment. He never operated on such cases if he could avoid it. As regards abscesses, one should always aspirate and never drain. In the radical cure of abscesses or other foci there were two principles: prevent infection from outside, and prevent infection from inside. He pointed out that in single hip disease the single Thomas hip splint was not efficient.

Mr. **Tubby** gave a short outline of the development of the campaign for the conservative treatment of surgical tuberculosis, and looked forward to the development of heliotherapy.

Dr. **Lockhart Stephens** (Emsworth) presented the point of view of the general practitioner, who ought to recognise early tubercle. Large costly institutions were in themselves unnecessary, as sun and fresh air are free.

Dr. **H. Scurfield** (late M.O.H., Sheffield) asked the percentage of cure at Alton, and stated that in his opinion sanatoriums only patched up the cases.

Dr. **T. H. Martin** (Leasowe) said that in the Liverpool clinics the single Thomas splint was not used for cases of tuberculous hip. He gave statistics of cure at Leasowe, and said that a history of familial tuberculosis in these cases was rare.

Mr. **McCrae Aitken** referred to the beginnings of the conservative treatment. Cases of bone tuberculosis must be rigidly excluded from contact with pulmonary cases. He agreed that the majority of surgical tuberculosis cases are not of human origin. He referred to his experiences with tuberculin, and stated that he had become frightened of it for orthopædic reasons—e.g., the possibility of ankylosis of a joint following a flare-up. He emphasised the absolute necessity for good and plentiful feeding.

Dr. **Camac Wilkinson**, asked by the Chairman to reply to questions raised, gave details of cure by tuberculin, and showed charts. He quoted recent statistics showing that in the large percentage of such cases the infection was human in type.

Mr. **Tubby** then moved a resolution to the Council of the Association expressing the high opinion of the Section of the value of modern conservative treatment, and their realisation of the necessity for the multiplication of institutions similar to those already existing. Dr. Scurfield seconded, and the resolution was carried unanimously.

Sir **Henry Gauvain** replied, quoting further statistics in favour of the human type infection. He took the occasion to thank Mr. Tubby for advice and help given in conservative treatment.

Milk Control and Tuberculosis.

Dr. **H. M. Cargin** (West Hartlepool) read a short paper dealing with the legal and public health aspects of this problem, and advocating the necessity of rigid control—e.g., in the inspection of dairy cattle. An interesting discussion followed.

Dr. **Scurfield** stated that he did not think that the use of pasteurised milk avoided the danger of bovine tubercle, and he strongly advocated dried milk.

Prof. **Brooker Mills** (Philadelphia) described the methods used in the U.S.A. to handle the problem—the city milk commissions and their regulations.

Dr. **J. D'Ewart** (Manchester) discussed the attitude of the farmer, and described the hospital milk-supply in Manchester. He did not think that dried milk was without danger.

Mr. **Elmslie** had seen scurvy, but not rickets, after the use of dried milk.

Dr. **Williamson** also referred to various points in the use of dried milk.

Demonstrations.

1. Cranioplasty, by Mr. **A. E. Morison** (Sunderland) who discussed the indications for the operation, and briefly described his methods. He showed eight cases and numerous X ray photographs.

2. Hydrocephalus, by Dr. **J. D. Lickley** (Newcastle), who discussed the symptoms and signs, the pathology, and the operative treatment. He showed several casts, pathological specimens, and photographs.

3. On Finer Adjustment: with Special Reference to the Hand, by Dr. **F. A. Hort** (Sunderland), who discussed certain refinements in the use of plaster and of splints, showing modifications of certain splints and some beautiful plaster casts of zoological and botanical specimens, illustrating the refinements of which plaster was capable.

SECTION OF AMBULANCE AND RED CROSS.

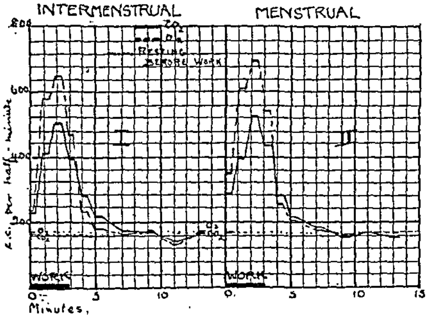
Wednesday, July 20th.

This section was well attended by medical men from Northumberland and Durham interested in ambulance work.

Sir **James Cantlie**, President of the Section, occupied the chair at the session, and opened the proceedings with a well-reasoned address on the

Claims of First-Aid to be regarded as a Special Branch of Practical Surgery.

He deplored the fact that such poor facilities were provided for the teaching of that important branch of is usually highest during the second minute of rest, and then falls slowly to normal with perhaps slight fluctuations. Although more of these experiments must be done before any definite conclusion can be drawn, the processes appear to be identical during the menstrual and inter-menstrual periods.



In conclusion, I wish to thank Prof. Winifred Cullis for suggesting to me this piece of work and for help and criticism during the work, and the Industrial Fatigue Research Board for the purchase of some of the necessary apparatus. I should also like to thank most warmly the subjects of the observations for their coöperation over a long period.

THE LATE PROF. G. T. LADD.—The death is announced at Newhaven, Connecticut, of George Trumbull Ladd, A.M., D.D., LL.D., emeritus professor of mental and moral philosophy, Yale University, author of "Elements of Physiological Psychology" and many other theological, philosophical, and psychological works.

PORTSMOUTH VENEREAL DISEASES NOTICES.—The affixing in public lavatories of notices giving instruction as to prevention of venereal diseases was discussed on August 9th at a meeting of the Portsmouth Town Council, when certain members of the council expressed their strong disapproval of the practice, stating their belief that it was an offence against decency, and that the notices were shameful and disgraceful. Other members pointed out that a visitor from the Ministry of Health had recently been to Portsmouth and had found no fault with the council's action in the matter; moreover, that action had been approved by a large conference of all the leading organisations of the town.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT NEWCASTLE-ON-TYNE.

SECTION OF ORTHOPÆDICS AND DISEASES OF CHILDREN.

WEDNESDAY, JULY 20TH.

AT the first session, Mr. A. H. TUBBY, the President, being in the chair, a discussion on the

Early Diagnosis and Treatment of Anterior Poliomyelitis

was opened by Dr. E. F. BUZZARD (London), who emphasised some of the frequent mistakes made in the diagnosis in the initial stages of this disease. He considered that given a more widespread recognition of the conception of acute poliomyelitis as one of the specific fevers of childhood, the clinician should be able to arrive at an early diagnosis with greater frequency. It was to be remembered that, contrary to the ordinary accepted teaching, pain was often a prominent symptom of the onset. Confusion sometimes arose in connexion with the resemblance of this disease to other acute infective conditions of the nervous system—viz., meningitis, toxic polyneuritis, Landry's paralysis, myelitis, and lethargic encephalitis. By careful examination it was usually possible to avoid errors from a clinical survey of the patient alone. A serological diagnostic test was theoretically available, but owing to the time involved was of little practical use. In approaching the early treatment of poliomyelitis it was essential to visualise the morbid anatomy of the disease. Treatment might be conveniently discussed under three headings representing stages in the progress of the condition: (1) the treatment of the patient who is ill with the disease, (2) the treatment of the patient during convalescence; and (3) the treatment of the resulting disabilities. During the first two stages a policy of inactivity, supplemented by several well-defined active measures, was indicated. The pyrexia and pain should be treated on the usual lines; in an epidemic, an immune serum, if available, should be given a trial, and the routine use of hexamine, although of doubtful efficacy, was to be regarded as reasonable. Physiological rest, however, was the great essential, and combined with it, the adoption of correct postures for the patient as a whole and for each portion of the body. The paralysed parts should be kept warm and their local circulation promoted by light rubbing. For about 18 months after the onset of paralysis varying degrees of recovery of function in muscles could be expected. This period was one of probation, and should be occupied by the continuance of muscle relaxation, and the preservation of contractility by interrupted galvanic stimulation of the individual muscles. The conventional electrical bath was both harmful and a waste of time. After a period of correct treatment extending over some 18 months, further mitigation of the patient's disablement depended on artifice or operation, these measures being provided by the intervention of the orthopædic surgeon.

Mr. R. C. ELMSLIE (London) laid stress on the practical value of early diagnosis with reference to the immediate application of the principles of complete rest. He advocated the routine use of complete fixation of the recumbent patient on a frame or preferably a plaster-of-Paris "bed." At this stage all physio-therapeutic treatment was to be condemned. In the position adopted for fixation the correct posture for the limbs was of course essential. In the stage of later convalescence, muscle re-education should be begun and it was important to remember that all active movements were to be carried out over a very small range in order to avoid the risk of fatigue. Later on, for the lower limbs, suitable walking instruments were absolutely essential, and unless devised and ordered by experts often merited the criticism which their use evoked. In the later stages, for the preservation of nutrition of the limbs, the simplest measures stones and the results. He showed that these calculi could be recognised and differentiated from renal calculi by their more anterior position (shown in lateral view) and by their structure—the presence of greater density in their peripheral parts.

Mr. J. W. THOMSON WALKER (London) showed that injection of the pelvis of the kidney with opaque material via the ureter would give an indication of the position of the kidney and the relation of the latter to biliary and renal calculi and calcified glands. The description was illustrated by slides.

Dr. E. P. CUMBERBATCH (London) opened a discussion on

Surgical Diathermy,

calling attention to the forms of active electrode which were used. These did not cause destruction to a sufficient depth of malignant growths. Deeper destruction could be procured by using disc end-pieces provided with prongs 10 or 15 mm. long. It could also be obtained if the tissue in contact with the end-piece were prevented from drying. This could be done by allowing salt solution to drip slowly on to the tissue around the end-piece. If the growth were freely movable and an attempt made to excise it by the blade end-piece, he advised that it should be first coagulated in situ before excising it. After reference to the regions of the body to which the diathermic cautery could be applied for malignant growths, the after-effects, the complications that might occur, and the duration of freedom from recrudescence, he described his experience in the use of diathermy for lupus, hæmorrhoids, and pigmented areas of skin. The results were encouraging and he thought that a more extensive trial of the method should be made.

Dr. C. W. S. SABERTON (Harrogate) said that he had obtained excellent results in the treatment of nævi of the mucous membranes by diathermy. In malignant growths of the mouth and throat diathermy produced better results than surgery, and at Harrogate the newer method was preferred. He described a case of naso-pharyngeal sarcoma in which diathermy procured freedom from recurrence for a much longer period than excision by the knife. The use of diathermy for amputating the cervix uteri, for cauterising fungating growths of the anus, vulva, and perineum, for relieving pain of hæmorrhoids and vesical spasm, was described.

Dr. F. H. HUMPHRIS (London) contributed a paper on the treatment of papillomata of the bladder and of corns by diathermy. The treatment of the latter consisted in first wearing away the hard tissue with a revolving steel burr and then with an emery wheel. A moist compress is kept in contact with the corn during the night, and the following day the centre is cauterised by fulguration.

Dr. WILLIAM HILL (London) said that after cauterisation, by diathermy, of malignant growths cicatrisation of the tissues occasionally occurred. Shock also sometimes followed the operation. He wondered why radium had not been used for the case of sarcoma described by Dr. Saberton, as this agent produced such excellent results in sarcoma.

Dr. H. E. GAMLEN (Newcastle) remarked that he had obtained good results in the treatment, by diathermy, of nævi of the mucous membranes and of hæmorrhoids.

THE EXHIBITION.

An exhibition of surgical instruments, drugs, foods, and other products of medical interest, arranged by Mr. W. E. WARNE, was open from July 19th–22nd in the St. George's Drill Hall, St. Mary's Place. Lighting and arrangements were good, an efficient restaurant with string band was provided, but the ventilation was very defective and made the life of the exhibitors needlessly irksome. In the following account the exhibits have been grouped in subjects, the reference number to the stall and catalogue in parenthesis.

Medical books were remarkably well represented by the exhibits of E. A. Brooke-Williams, London (24), H. R. Ellis, London (61), H. K. Lewis & Co., London (13), Oxford Medical Publications, London (54), R. Waugh, Newcastle (22), and John Wright and Sons, Bristol (61).

Instruments.

There were five large exhibits of general surgical instruments: Down Bros., London (68), showed a collection of original models carried out at the suggestion of surgeons; J. Gardner and Son, Edinburgh (28), a number of instruments made in rustless steel; Mayer and Phelps, London (21), instruments for many special purposes including anæsthetics and clinical diagnosis; John Weiss and Son, London (5), a complete equipment for general and ophthalmic surgery; R. Whitelaw, Newcastle (12), up-to-date instruments along with a selection of splints, limbs, and boots. Special exhibits by Robert McQueen and Son, Newcastle (33), of instruments designed by surgeons on the staff of the Royal Victoria Infirmary, and the Genito-Urinary Manufacturing Co., London (60), of cystoscopes, urethroscopes, pharyngoscopes, &c.

Of scientific appliances, the Cambridge and Paul Instrument Co., London (37), exhibited an electrocardiograph, a Mackenzie-Lewis polygraph, a Woodhead-Varrier Jones recording clinical thermometer outfit; Hawksley and Sons, London (80), polygraphs by Mackenzie and Jaquet, sphygmomanometers, electrical diagnostic and anthropometrical instruments; Chas. Hearson and Co., London (63), electric incubators, all-metal wide range thermostatic ovens, autoclaves, myographs, and the like; Ogilvy and Co., London (45), microscopes, microtomes, epidiascopes.

Artificial Limbs and other Appliances.

A wide range of other appliances was on view including six exhibits of artificial limbs: Anderson and Whitelaw, Birmingham (70), a selection of light dress arms, workers' arms, and the implements for use with them; F. G. Ernst, London (71), specially concealed appliances for poliomyelitis, ununited fractures, and rheumatoid arthritis; W. R. Grossmith, London (72), arms and legs adapted to particular amputations; M. Masters and Sons, London (69), light Anglesea legs and other appliances; Peet, Gilman and Company, Newcastle (29), willow and light metal limbs in many forms; P. K. Arm, Belfast (75), a mechanical arm with gripping hand and safety leg with automatic knee lock.

Hospital beds and equipment including the Alton portable bed were shown by Hoskins and Sewell, Birmingham (2); a folding chair and sun-blind for sanatorium use by Institution Requisites Co., Birmingham (73); and fracture apparatus on portable tubular bed-frame, embodying the lessons of the war, by Robert Morison Edinburgh (35).

X ray outfits and tubes along with a handy "hot-point" immersion heater were in the exhibit of the British Thomson-Houston Co., London (62); materials for radiant heat treatment in that of the Dowsing Radiant Heat Co., London (36); radio-active applicators in standard sizes in that of the Kramer Radio Active Applicators, Birmingham (66); electrical aids for the deaf in that of W. H. Pettifor, London (59); and Edridge-Green lanterns and tests in that of Rayner and Keeler, London (41). Kodak (67) had an exhibit of X ray films and developing tanks.

Drugs and Chemicals.

Fine chemicals had a large place in exhibits by Brady and Martin, Newcastle (79), who made a point also of animal extracts, and by Phillips Spencer, Dakers and Co., Newcastle (40), along with crude drugs and compressed tablets. Pharmaceutical preparations were shown by Anglo-French Drug Co., London (56), galyl, ambrine, cuprase, dimol, &c.; Genatosan, London (53), sanatogen, formamint, detoxicated vaccines; C. J. Hewlett and Son, London (4), evapogens, veronigen, somnigen, &c.; Howards and Sons, Ilford (82), standard ether, agotan, optochin, &c.; W. Martindale, London (46), amyl nitrite, animal extracts, sterules, vaccines, &c.; Oppenheimer, Son and Co., London (1), palatinoids, pulverettes, roboleine, &c.; Parke, Davis and Co., London (47), metagen, hemoplastin, hormone preparations, phylacogens, &c.;

næsthesia in children under one year, and occasionally n children a little older. If complete reduction was not obtained at one sitting it was advisable to effect t in stages. After correction fixation should be kept up for a considerable period and preferably by means of a well-fitting plaster. The after-treatment was o be along the lines of the early postural treatment. Where the contracture could not be stretched by manipulation alone the open operation for division of the shortened structures was indicated. This might include, n addition to division of the subscapularis tendon, the coraco-humeral ligament and even the conjoined tendon of the biceps and coraco-brachialis. The original technique of Fairbank for the open operation has been modified with advantage by Sever, and in the experience of the writer could be expected to give satisfactory results provided the period of post-operative fixation was short and stretching and re-education were begun early.

No discussion followed the papers of Dr. Jansen and Mr. Platt owing to the limited time at the disposal of the Section.

THURSDAY, JULY 21ST.

At the second session, with Dr. H. MORLEY FLETCHER (London) in the chair, a discussion took place on

Blood Diseases in Children.

Dr. HUGH THURSFIELD (London), in introducing this subject, said that though it was now nearly eighty years since the discovery of the disease leukæmia had ushered in a period in which these diseases had been studied carefully by clinicians, it might at first sight appear that there had been little or no progress made. Yet if we considered the state of knowledge 20 years ago he believed that it was possible to demonstrate that the progress, though slow, was sensible. Our ideas on classification and differentiation of the diseases were clearer and more definite. He went on to plead for new methods in the study of blood diseases, contending that there had of late been too much concentration on what appeared to him to be the somewhat sterile study of the origin and nature of the white cells of the blood, while we were still grossly ignorant of the functions of most of these. Premising that he was about to lay down propositions in a more dogmatic manner than either his knowledge or his judgment permitted, he proceeded to classify the diseases under discussion into three groups: (1) congenital; (2) secondary; (3) primary, anæmias. For the purposes of the discussion he attempted to define exactly what is meant by anæmia, and the criteria of the different types. After some remarks on the congenital states of the blood, and on the secondary anæmias, he briefly discussed the nature of von Jaksch's pseudo-leukæmic anæmia of infants and then passed on to the problems of the primary anæmias. Again, for the purposes of discussion he proposed that there were only three types of severe primary anæmia known below the age of puberty—leukæmia, purpura, and that which he proposed to call the anæmia gravis of children. This last was perhaps more commonly known as aplastic anæmia, a name to which he took exception since it appeared to him to be a descriptive term applicable to some stages of any severe anæmia. Discussion of some of the problems of leukæmia followed, and he dealt with the differentiation of "aleukæmic leukæmia" and anæmia gravis. For this last type he insisted that its origin was infective, and that, like its analogue in the adult, pernicious anæmia, it was not a clinical entity. Remarks on treatment the success of which, in the speaker's opinion, depended entirely on the successful detection of the focus of infection brought the paper to a conclusion.

Prof. BROOKER MILLS (Philadelphia) opened the discussion with some appreciative criticism of the introducer's main contention that the cause of these complaints must be looked for in infective processes. He then referred to hæmophilia as possibly a congenital disease of the hæmopoietic system. He concluded by illustrating from his own and his colleague's experience the influence of hidden foci of infection on several remote organs or systems.

The CHAIRMAN did not agree with the introducer that the subjects of anæmia gravis were chiefly drawn from the hospital class of the community. He was inclined to think that it was not infrequently met with in well-to-do families, though in no class a common disease. He also doubted whether so sharp a line could be drawn between the different forms of the primary anæmias as Dr. Thursfield had suggested, considering that there were stages in the course of some of the acute leukæmias which it was impossible to distinguish from anæmia gravis.

Dr. J. F. GASKELL (Cambridge) agreed with the introducer that newer methods were eminently desirable in this field of knowledge and gave a very brief account of the trend of some researches at present being made at Cambridge by Dr. Howard Vines on the behaviour of the calcium content of the blood. Though the direct bearing of these researches on the clinical problems which they were considering was not obvious, it was clear already that the variation in the calcium had a profound effect on the whole hæmopoietic system.

Dr. JOHN THOMSON, Dr. LEONARD FINDLAY, and Mr. TYRRELL GRAY also contributed brief remarks; the first dealing principally with that mysterious disease melæna neonatorum, an unusual case of which was shortly described by Mr. Gray. Dr. Findlay thought that the introducer was mistaken in excluding Banti's disease from the category of children's anæmias, and made some interesting general criticisms on the subject of the debate.

Dr. THURSFIELD made a brief speech in conclusion.

Short Papers.

After the conclusion of this debate Dr. FINDLAY read a short paper on the Pre-natal Treatment of Syphilis, in which he advocated this method as the only satisfactory means of controlling congenital syphilis. The treatment of the infant after birth he regarded as quite definitely a failure, whereas the treatment of the pregnant woman had in his hands produced very favourable results.

This paper was discussed by Prof. BROOKER MILLS, Dr. A. A. S. SKIRVING, Dr. IVY MACKENZIE, and others, who for the most part were in agreement with Dr. Findlay. A resolution was passed by the Section calling the attention of the Council of the Association to the matter with a view to the earlier and more complete recognition of the syphilitic mother.

Dr. JOHN THOMSON then read a short paper on Some of the Problems of Hypertrophic Pyloric Stenosis, and Mr. TYRRELL GRAY discussed the surgical aspects of the same disease, based on the operation of some 50 cases at the Hospital for Sick Children, Great Ormond-street.

Dr. MORLEY FLETCHER, Mr. PAGE, and Dr. FINDLAY contributed remarks, but the discussion was prematurely closed owing to want of time.

FRIDAY, JULY 22ND.

Tuberculosis of Bone in Children.

At the third session, Mr. R. C. ELMSLIE being in the chair, Sir HENRY GAUVAIN opened a discussion on the General Principles of Treatment in this condition, pointing out that in 1912 Sir Harold Stiles advocated radical measures in the treatment of bony tuberculosis in children, while shortly afterwards, Mr. TUBBY, in opening a discussion on the subject at the Royal Society of Medicine, urged the adoption of conservative treatment, which was now the more general method of choice. The fundamental principle of all treatment was based on the fact that the condition is an osteitis or osteoarthritis occurring in a tuberculous child, such a lesion being secondary to an infection, and that therefore one must treat the patient generally. In the blood and urine were antigens present before the disease was clinically manifest; and some held that they could demonstrate tubercle bacilli in the blood at this early stage. As a general disease demanded general treatment, he was at present in favour of conservative treatment—i.e., designed to improve the patient's resistance, and to unable to subscribe without reservation to the infective view so cogently urged by the author, he will read with satisfaction the publication of this scholarly monograph.

Inguinal Hernia, the Imperfectly Descended Testicle and Varicocele.

By Philip Turner, M.S., F.R.C.S., Assistant Surgeon, Guy's Hospital. London: J. and A. Churchill. Pp. 104. 9*s.* 6*d.*

The author who sets himself the task of writing a monograph upon hernia, the undescended testicle, or varicocele, has indeed a difficult problem in front of him. These common conditions are within the possibility of study of a multitude of men, and for that reason have always received an immense amount of attention and thought. If an individual is to add to knowledge he must be ingenious in his originality, or bring forward the after-results of a large series of cases, and it is by this high standard that we must judge such monographs. This volume of 104 pages contains much sound advice in the treatment of the average case, but it does not help the practising surgeon in dealing with just those problems in treatment which still await solution. In the treatment of hernia there is one principle upon which the author insists which does really seem of importance—the careful avoidance of injury to muscle fibres by dissection, or strangulation by suture. The observance of this more generally might well reduce the number of recurrences. We look in vain for guidance in the treatment of recurrent hernia, or of those cases in which the conjoined tendon is feebly developed; nor does Mr. Turner describe the recurrence which breaks through the inner end of the posterior wall of the inguinal canal after the cure of an indirect inguinal hernia, though it must have been his fate to deal with these difficult relapses. It would have been of interest to hear his views of the value of such measures as the transplantation of the rectus muscle, or its sheath, or the use of a fascial transplant.

Mr. Turner has gained more success in orchidoplasty than have most surgeons, and this he attributes to his careful division of fascial bands in the cord, and to the method of fixation of the testicle in the opposite side of the scrotum. We cannot agree that " it is certainly very unusual for there to be any difficulty in transplanting the testicle to the scrotum "; even after division of all fascial bands a certain proportion of testicles will not reach the scrotum without tension. His percentage of successes demonstrated—viz., 50—is a very creditable performance in this unsatisfactory condition. As for the varicocele operation the method of suspension is an advance, but here also an account of results would have made interesting reading.

The Sex-Complex.

Second edition. By W. Blair Bell, B.S., M.D. London: Baillière, Tindall and Cox. 1920. Pp. 251. 21*s.*

We cordially welcomed the first edition of this book and are not surprised that a second has been called for. It is with regret that we note that the author does not intend to publish any further editions. That the labour of keeping such a book up to date is very onerous we have no doubt, but we cannot agree with him that " this is not the kind of book that can usefully be taken through numerous editions," for it will always require a skilled assessor to decide the relative importance of various new observations as they are made. The ordinary reader has neither the time nor the knowledge necessary for this and is apt to become confused both by the abundance of the material and the apparent discrepancies contained therein. Inasmuch as a beginning can now be made in forming generalisations, the opinions of such an assessor as Dr. Blair Bell will have special value, for it requires personal experience in original work correctly to evaluate the work of others.

It should be made clear that Dr. Blair Bell does not use the word " complex " in the psychological sense; his subject is the correlation between the female reproductive organs and the endocrine glands, and the way in which these interact with one another in health and disease. The essential fact, as he says, is that femininity itself is dependent on *all* the internal secretions. These profoundly influence both the psychology of the individual and the general metabolism, which in turn is influenced to subserve the necessities of the special functions. These aspects, metabolic and psychological alike, are discussed in an interesting and illuminating manner.

The Endocrines.

Sympathetique and Glandes Endocrines. By Lereboullet, Harvier, Carrion, and Guillaume. Being Vol. IX. of Traité de Pathologie Médicale et de Thérapeutique Appliquée. Paris: Maloine et Fils. 1921. Pp. 350. Fr.18.

Few subjects in medicine are attracting more attention to-day than the relations between the sympathetic nervous system and the endocrine glands. This volume of the Traité de Pathologie Médicale et de Thérapeutique Appliquée is therefore specially welcome. After a general study of the endocrine glands the pathology of each is considered. Then follows an account of the anatomy and physiology of the sympathetic nervous system, and of its pathology. The last section deals with organotherapy. The diagrams we have found excellent; they make it easy to understand the arrangement of the sympathetic nervous system. The chapter on the pathology of this system might well have been amplified, and three pages would appear far too little to devote to the endocrino-sympathetic syndromes. Just as the nervous system as a whole was evolved both for internal integration and for directing the external life of relation, so the sympathetic, as the lowest level of the nervous system, directs the functions of organic life and activates the body for defence against the external foe. In the accomplishment of this task it has entered into an alliance with the endocrine glands, which represent a specialisation of the older chemiotropic methods of defence, and the essential feature of disease of the endocrino-sympathetic apparatus is that it is a perversion of the primitive defensive mechanism.

Individually the sections of the book are nearly all excellent, whilest defects are no doubt due to the fact that the different sections are from the pens of different authors. A chapter correlating them would have materially enhanced the value of the book as a whole.

Treatment of Diseases of the Skin.

Third edition. By W. Knowsley Sibley, M.D. London: Edward Arnold and Co. 1920. Pp. 248. 12*s.* 6*d.*

This book, which has now reached its third edition, contains some useful information, and a number of the prescriptions given are of real value. It is not, however, a scientific treatise, in spite of the fact that the author claims, in his preface to the first edition, that the treatments given " are thoroughly up to date " and " possibly in some cases a little in advance of many of the generally accepted principles of the present school of dermatology in this country."

Although some sound observations are made on the influence of diet and of abnormal conditions of the alimentary tract in the causation of certain skin diseases, the directions for internal treatment are too often as vague as the author's views on ætiology. Herpes zoster, we note, may be produced " by atmospheric changes, exposure to cold and wet, sudden checking of perspiration, traumatism, peripheral nerve irritation or injuries, pulmonary diseases, intestinal parasites, malaria, carbonic acid gas poisoning, arsenic, reflex nerve irritation, such as dental troubles, &c. "; hyperidrosis " is probably due to faulty innervation," and Raynaud's disease " has followed cold, exposure, general disturbances of nutrition, severe systemic disease, various neuroses, and nephritic disorders." These excerpts are taken at surgery. For instance, when they went to any of the big railway stations to teach first-aid, they generally found that nothing better than an old shed was placed at their disposal. The marvel was that first-aid had done so well; but they knew that it could do much better. The speaker recalled that his first class was held below the arches of Charing Cross station. To light that apartment all they had was a candle stuck in an empty bottle, and they drew their diagrams on a piece of white paper pinned up on the wall. Surely such an important branch of surgery was worthy of better teaching accommodation than a shed. He went on to tell how interest in first-aid work in this country really dated from a medical and sanitary exhibition held at South Kensington in 1881. Interest was first taken by German universities and hospitals in the subject, and it was Germany which taught the world military ambulance, although it was England which taught civil ambulance. Despite that, no British university had yet asked for a first-aid class to be held within its sacred walls.

In regard to its practical application the speaker pointed out that when a man received a hurt or a wound the danger period was in the first 20 minutes, therefore it was during that period that first-aid was so important, for everything depended on how the injured person was then treated. Who was it that had charge of the injured person during that critical period in civil life? It was the public, and it was from that standpoint that the question must be considered. He went on to speak of the delight of improvisation which after all was at the basis of first-aid work. He approved of ready-made appliances, but said they were seldom to hand when required. The danger he saw to-day was that the training was approaching too near to the study of medicine. If that went on they would be up against the doctors, and the result would be that the public would have to take up the teaching of first-aid. In conclusion, Sir James Cantlie paid a tribute to the doctors and ambulance men of Northumberland for the magnificent work they had done. He advocated strongly the establishment of colleges of ambulance in the chief centres in this country. "Give them their proper name, and give men a better and higher notion of what is the meaning of first-aid," he added.

Dr. **ROBERT ANDERSON**, Vice-President of the Section, said that during 40 years of teaching ambulance work in the North of England he had instructed thousands of persons, and he gave several examples of the instruction having been turned to practical account. He saw no reason why every man should not have some knowledge of ambulance work, and he approved of the scheme for the establishment of colleges of ambulance.

Sir **JAMES CANTLIE** then unfolded a scheme for an

X Ray Motor Ambulance Wagon Service

for Great Britain, describing the work in London and district, where such an ambulance had been provided by the Eccentric Club, an agency which had done much good in an unostentatious fashion. The question was a humanitarian one, and he was sure they would have no difficulty in obtaining the money to establish the service. With the aid of a display map the President showed how centres could be established throughout the country from which areas could be worked. He then demonstrated the value of the yoke sling, with which to carry a stretcher, condemning the old-fashioned sling, which put all the weight on the neck, and also the carrying of a loaded stretcher on the shoulders. With the yoke sling, modelled on the lines of the farm worker's yoke, two women could carry a man on a stretcher, whereas without it six women would be needed.

A discussion was contributed to by Dr. W. **NUNAN** (Bombay), Dr. J. G. D. **CORT** (Whitburn), and Dr. C. H. **MILBURN** (Ministry of Health).

SECTION OF ELECTRO-THERAPEUTICS AND RADIOLOGY.

FRIDAY, JULY 22ND.

Dr. R. **KNOX** (London), in his Presidential address, stated that the blood was especially suitable for investigation of the action of radiation on the living tissues. He emphasised the need for further precaution by the operator against the action of the rays on himself. He referred to the method of X ray treatment practised at Erlangen and regretted the recent statements in the press that cures of cancer were being obtained. These statements, he said, were premature, and judgment should be withheld until this method had been given an adequate trial in this country. The position of the radiologist in the treatment of malignant growths should be reconsidered. Surgery was the treatment to be given first, but combined treatment by surgery and radiation was better than either singly, and more radiation should be given than is the case at present.

Prof. G. L. **GULLAND** (Edinburgh) opened a discussion on

Radiation in the Treatment of Diseases of the Blood.

He showed that radiation should be used in diseases in which there was hyperplasia of the blood cells rather than hypoplasia, in the leukæmias rather than in the anæmias. If, in the future, the stimulating action of radiation could be increased and the destructive action excluded, the anæmias, especially pernicious anæmia, might be successfully treated. Radiation, when excessive, is able to exhaust the bone-marrow function and produce an aplastic anæmia, after a preliminary anæmia with a high colour-index. X rays should be more systematically tried in polycythæmia vera. The three main varieties of leukæmia react very differently to X rays. In acute lymphatic leukæmia X rays are useless and probably harmful. Chronic myelocythæmia responded best to treatment by radiation, and the speaker preferred radium to X rays. The neutrophiles were most affected and the normoblasts disappeared rapidly. Degenerated cells were found in large numbers in radiated blood. The speaker regarded a reduction of the white count to 20,000 as a signal for stopping the radiation. He regarded splenic anæmia as one of the most hopeful conditions for treatment by radiation. It seemed to him that the problem of the future is the determination of accurate dosage. The evil effects which radiation can produce may complicate the diseases treated by this means.—Prof. S. **RUSS** (London) showed that certain measured doses of X rays produced constant changes in the number of the lymphocytes, whereas the changes in the number of the polymorphs are quite irregular. After large doses of radium a greater regularity was observed in the behaviour of the lymphocytes than the polymorphs.

Dr. J. C. **MOTTRAM** (London) read a paper on

The Use of Blood Counts to Indicate the Efficiency of X Ray and Radium Protection.

He showed that exposure to radiation was followed by a diminution in the number of lymphocytes and polymorphonuclear leucocytes in the blood, and, to a less extent, of the red corpuscles. If these changes were noted in X ray and radium workers, and if they were persistent, they indicated that there was insufficient protection. He showed that it was necessary, when making blood examinations, to determine, not the normal limits of variation in the number of the corpuscles, but the normal distribution of variation, so that when a low count is recorded, its value can be estimated.—Dr. A. **LEITCH** (London) maintained that the diminution in the number of the lymphocytes following an exposure to radiation was a physiological process, and could occur after mental disturbance. He had obtained a similar diminution in rats which showed fright when exposed to the apparatus which was in operation without the production of radiation.

X Ray Diagnosis.

Dr. **KNOX** read a paper and showed lantern-slides to illustrate his method of X ray examination for gall-crude, and some of them are quite misleading, as, for example, Figs. 3 and 4 on Plate 44, purporting to represent sections through a stoma and a lenticel respectively, and Fig. 3 of Plate 46, intended to represent the laticiferous vessels (described as "tubes") of taraxacum root. The careless drawing on the 69 plates is sufficient in itself to mar the value of the book as a guide for the beginner. Moreover, that the information given is not always trustworthy may be seen from the following quotation (p 129): "Closed collateral bundles consist of a xylem portion and a phloem portion separated from each other by a short strip of cambium, the whole being surrounded by a sheath or layer of fibrous tissue."

CHEMISTRY.

A System of Physical Chemistry. Vol. II., Thermodynamics. By W. C. McC. LEWIS, M.A., D.Sc. London: Longmans, Green and Co. 1920. Pp. 454. 15*s*.

THIS volume is one of the well-known series of text-books of Physical Chemistry edited by the late Sir William Ramsay and Prof. F. G. Donnan. Thermodynamics deal with the laws and relationships which govern the quantitative transformations of energy of one sort into energy of some other sort during physical or chemical changes in the system. The characteristic feature of this extremely interesting and important branch of physical chemistry is that one can deal with energy changes involved in a physical change of state or in a chemical reaction without requiring information regarding the molecular mechanism of the process under investigation. The school of physical chemistry, notwithstanding the eloquent criticism of Prof. H. E. Armstrong, is an ever-increasing force in this country, and Dr. Lewis's work will doubtless be regarded as a real contribution to a subject which to the non-expert appears highly mathematical and complicated.

Applied Chemistry. A Practical Handbook for Students of Household Science and Public Health. Vol. I. By C. K. TINKLER, D.Sc., and HELEN MASTERS, B.Sc. London: Crosby Lockwood and Son. 1920. Pp. 292. 12*s*. 6*d*.

ALTHOUGH it would appear that this volume is primarily intended for those students who are reading for the Diploma in Household and Social Sciences recently instituted by the University of London, yet it deserves a better fate than to be regarded simply as a text-book associated with a particular academic institution. The subjects dealt with are water analysis, water softeners and "soda" substitutes, soap, textile fibres, bleaching agents, dry cleaning, air analysis, gaseous fuels, liquid and solid fuels, and materials used for the protection of wood, metal, and other surfaces. The ground the authors have covered is considerable, but nevertheless their treatment of it is well balanced and the selection of experiments wisely conceived. Portions of the volume may well be read by students preparing for diplomas and degrees in public health.

MY LADY'S GARDEN.

Planted and Grown by HACKLEPLUME. London: Watts and Co. 1921. And from Hackleplume, 120, Grosvenor-road, S.W. 1. 25*s*.

THE author closes a sumptuous gift-book with an apostrophe to "The Tortoises who Dwell in the Waters of Lethe," in which she appears to plead for any notice rather than no notice. By the help of the index, which the reviewer—i.e., the Tortoise Who, &c.—is requested to read for the better understanding of the "garden," we gather that the verses are a tribute to all soldiers, sailors, and civilians who took part in the war. The work is divided into 19 sections, each section dealing with a different arm of the forces, or geographical unit, and throughout the verses the names of officers and men are associated with particular flowers, the reasons, given in the footnotes, being calculated sometimes to raise blushes on the cheeks of modesty. The reason for sending the book for review to THE LANCET is that one of these sections is entitled "The Physic Garden," and here various officers of the R.A.M.C. are noted as camomile, vanilla, genista, and so on.

Hackleplume is not a poet, but she is evidently full of her theme, and amidst passages of triteness, triviality, and slanginess happy lines occur. She has felt the splendours and tragedies of the war deeply, and has striven to give expression to the emotions evoked. It would not be fair to criticise more closely a work whose inspiration has been a blend of pity and patriotism. The book is illustrated by Miss Marjorie Raynor in the decorative style of flower painting which delighted the public in the middle of the nineteenth century. None of the flowers are drawn to scale, and profound liberties are taken with their hues, but the patterns made are decorative, and the technique is quite dexterous. The reproductions are good.

JOURNALS.

Journal of Industrial Hygiene. London: Macmillan and Co., Ltd. 4*s*.—Output continues to be studied as a measure of human activity. The May issue of this Journal contains an article of some interest in which the influence of tobacco upon physical efficiency is measured by this means. The process studied was that of blowing glass by machinery, during which moulds are fed with "gobs" of molten glass by a man who gathers the required amount from a furnace. The number of "gobs" gathered hour by hour throughout the day were counted, allowances being made for their size. Then the work of heavy smokers, light smokers, non-smokers, and of those who chewed tobacco was compared. Smoking was found to have little effect upon the rate of output in this occupation, which calls for strenuous physical exertion. Indeed, the light smokers had a slightly lower rate of output than heavy smokers. Chewing, on the other hand, was found associated with a definitely lower rate of output. The conclusion with regard to smoking is curiously at variance with the accepted tradition of athletes, but the data upon which it is based are substantial enough to merit consideration.—Appeal is made in the July number by Dr. H. M. Vernon to morbidity and mortality records as measures in estimating the influence of fatigue on health and longevity. Dr. Vernon's paper deals exclusively with the English iron and steel trade, in which he has carried out an extensive investigation. The sickness experienced in this industry is due for the most part to respiratory affections and forms of rheumatism; older men from 55 to 69 years of age were found to lose 6·5-fold more time from rheumatism than younger men of 16 to 20, an excess which was more marked among those working at high temperatures, where the older steel melters and pitmen lost no less than 7·7-fold more time than the younger men. Older engine men, on the other hand, lost only 3 to 5-fold more time from rheumatism than younger men. The tables given are held to establish that exposure to weather is causative of excessive sickness from rheumatism and respiratory diseases. Mortality data were found to support closely the conclusions drawn from morbidity records; here an interesting fact emerges: that exposure, such as working in the open air, which may increase the risk of respiratory diseases in general, may actually reduce the tendency to phthisis. In this excellent study Dr. Vernon sees reason to conclude that in men of good physique the fatigue of heavy work has but little direct effect on sickness and longevity, and that the heavy work of iron puddlers, of tinplate mill men, and of rolling-mill men, has no injurious effect on health except indirectly, when it induces men to sit about in damp clothes. This conclusion, that the harmful conditions of the occupations studied depend rather upon environ-

Savory and Moore, London (15), ethanesal, fructolax, datura tatula asthma remedy, &c.; W. A. Wharram, Leeds (55), *pepsin preparations, concentrated mixtures, cascalax, laxatol*, &c.; Wyleys, Coventry (50), *antiseptic jellies, bromchloral, elixirs, wylettes*, &c.

Single preparations formed the whole exhibit in the case of the Anglo-American Oil Co., London (30), nujol, an intestinal lubricant of constant viscosity; Clement and Johnson, London (43), yadil antiseptic (allylic carbide) as a liquid, ointment, soap, &c.; Crookes Laboratories, London (25), collosols, the physical characteristics visible under the ultramicroscope; Jeyes' Sanitary Compounds Co., London (42), cyllin, an antiseptic of high bactericidal power and low toxicity; Kress and Owen Company, New York (agents, Thomas Christy and Co., London) (14), glycothymoline, an antiseptic solution based on the alkalinity and saline strength of the blood; Pepsodent Company, London (38), pepsodent, a dentifrice with an acid reaction due to acid calcium phosphate; Wm. Browning Co., London (34), semprolin, a liquid paraffin of standardised viscosity.

Food Products.

Three milk products were shown: Hooker's malted milk (27) claimed to retain the vitamins and to be free from cane sugar and starch; Horlick's malted milk (48), a modified milk containing cereals in which the starches have been hydrolysed by diastase; Glaxo (39), a standardised and desiccated milk, used as a complete infant food. Chocolate was on exhibit by Cadbury Bros., Bournville (18); meat preparations by Brand and Co., London (44), with various essences and beef teas; and Oxo, Limited, London (49), with oxo, lemco, and other concentrated foods; yeast and malt preparations by Calder's Yeast Company, Newcastle (31). Special nutritive substances were on the stands of Mawson and Proctor, Newcastle (3), in the form of majax sugar of milk for humanising cow's milk; Numol, Newcastle (32), a lecithin food rich in vitamins, for use in rickets, marasmus, &c.; Sanagen Works, London (20), a casein-glycerophosphate combination in various forms; Virol (16), a preparation rich in animal fats, used in cases of malnutrition, also as virolax combined with paraffin. Wm. Gaymer and Son, Attleborough, Norfolk (17), showed samples of cyder for patients with gouty or rheumatic tendency.

Spas and Mineral Waters.

A series of six similar stands illustrated the attractions of British inland watering places—namely, Bath (6), with its daily yield of half-a-million gallons of highly radio-active water at 120°F.; Buxton (7), the mountain spa with warm radio-active mineral water at 82°F. and other chalybeate springs; Droitwich (8), with its brine baths containing more than 20,000 grains of salts to the gallon; Harrogate (9), with 87 springs, 16 used internally, divided into sulphur alkaline, saline, and chalybeate; Leamington (10), the Midland spa, with dry equable climate and a natural aperient and diuretic water; Woodhall spa (11), with its spring of water containing bromine and iodine in high degree. The Apollinaris Co., London (26), showed the sparkling table water of the Apollinaris spring and the gently purgative apenta water; Ingram and Royle, London (65), showed natural mineral waters, bottled and in tablet form, from English, French, and other foreign medicinal springs.

Miscellaneous.

Several exhibits touched nearly on the hygiene of the person and the home. The exhibit of the British Commercial Gas Association (76) bore on the abatement of the smoke evil; that of the British Electric Transformer Co., London (58), on the convenience of electric heating and cooking. The Cellular Clothing Co., London, showed the points of aertex material for health and comfort; Ronuk, Portslade, Sussex (52), the use of sanitary polish and floor materials; Sapon Soaps, London (51), the value of neutral saponified cereals in removing dirt and grease.

The Medical Insurance Agency (78) and the Medical Sickness, Annuity and Life Assurance Society (81), both had prominent exhibits.

Reviews and Notices of Books.

GOUT.

By LLEWELLYN JONES LLEWELLYN, M.B. Lond., Senior Physician, Royal Mineral Water Hospital, Bath. With a section on Ocular Disease in the Gouty. By W. M. BEAUMONT, Consulting Ophthalmic Surgeon to the South-Western Region of the Ministry of Pensions. London: William Heinemann, Ltd. 1920. Pp. 469. 30*s*.

IN reading the preface to his book it is realised that Dr. Llewellyn is a whole-hearted adherent of the view that an infective element plays an important part in the genesis of gout. In the body of the work he finds good reasons for dismissing rival theories as inadequate to explain the pathogenesis of this disease, but we have failed to find any allusion to the modern view that an attack of gout may possibly be an anaphylactic phenomenon. While holding that microbial infection is the causa causans of an attack of gout, the author admits that this infection would not produce the characteristic phenomena if there were not already a constitutional predisposition. "Gout," he says, "is an hereditary disorder, the *intrinsic* element of which is an inborn instability of nuclein metabolism which may remain latent, but under the influence of *extrinsic* factors, *infections*, become manifest, as betokened by local inflammatory tissue reactions in joints or elsewhere, the specific character of which is attested by the associated *uratic deposition*." Dr. Llewellyn is of the opinion that the presence of tophi "either clinically demonstrable or deducible from skiagraphic revelations," is the solitary unequivocal criterion for a clinical diagnosis of gout. Examples of non-tophaceous, deforming gout he believes to be largely made up of the atrophic and hypertrophic forms of arthritis deformans.

The first 200 pages of the book are devoted to a consideration of pathological and bio-chemical data and to a discussion of the various theories which have been put forward to explain the nature of gout. While not primarily of interest to the pure clinician, the fascination and lucidity of Dr. Llewellyn's style make every page worth reading. With Chapter XVI. we come to the excellent clinical account of the disease, the detailed consideration of which runs into some 50 pages. Five chapters dealing with clinical diagnosis, including skiagraphic results, then follow. The author is of the opinion that the resemblance between skiagrams of chronic gout and rheumatoid arthritis is so close as to forbid reliance being placed solely on skiagraphy to effect a differential diagnosis. Skiagraphy cannot be allowed to usurp the place of careful clinical observation. A delightful chapter follows on irregular gout, opening with Benjamin Rush's century-old dictum: "It is not a sacred disease. There will therefore be no profaneness in handling it freely"; counsel of which the author takes full advantage. Mr. W. M. Beaumont contributes a chapter dealing with certain ocular defects occurring in gouty subjects, and enters a plea for a more systematic and scientific investigation of the true link, if such exist, between iritis and arthritis. The final chapters are devoted to a consideration of treatment. While much space, as might have been expected, is given up to hydro- and climato-therapy, medicinal agents like colchicum, the iodides, atophan, come in for full attention. Colchicum and salicylate of soda act quickly or not at all. "Because of our unreasoning devotion, our almost fetishistic addiction, to these drugs, I often feel that these agents, especially salicylate of soda, have made more cripples than they have saved."

In spite of Dr. Llewellyn's views on the infective origin of the disease we notice that he devotes little space to vaccine therapy, to which there is only a single reference in the excellent index appended to the volume. It is only fair to say that radical treatment of local foci of infection and toxic absorption is duly insisted upon. Even should the reader be repeated after exertion. Their figures show that the dyspnœa in uncompensated heart cases cannot be entirely explained in terms of an increased acidity of the arterial blood. Neither can the dyspnœa be explained in terms of an altered content of oxygen and carbon dioxide in arterial blood. These negative results lead to the hypothesis that cardiac dyspnœa is due to reflex stimulation of the respiratory centre, brought about in part by venous stasis in the pulmonary circulation, and in part by an increase in the carbon dioxide in the alveolar air.

Reports and Analytical Records.

(1) "WELLCOME" BRAND ANTI-PNEUMOCOCCUS SERUM, TYPE 1; (2) "WELLCOME" BRAND AGGLUTINATING SERUM, PNEUMOCOCCUS, TYPES 1, 2, OR 3.

(BURROUGHS, WELLCOME AND CO., SNOW HILL BUILDINGS, LONDON, E.C. 1.)

1. THE therapeutic serum is issued in phials of 25 c.cm. for use in cases of pneumonia caused by pneumococcus Type 1. The makers state that the usual practice is to give 50 to 100 c.cm. intravenously as soon as Type 1 pneumococcus has been identified by one of the usual methods. The mouse method and the culture-tube method are described. This determination is a necessary preliminary to treatment, for no benefit can be expected from this serum in cases of pneumonia, where the causative agent is Type 2, 3, or 4. The intravenous injection can be repeated twice a day until definite improvement occurs, an average case receiving from 200–500 c.cm. in all. Since symptoms of shock have been known to follow the intravenous injection of serum some clinicians prefer to test the patient for sensitivity by a preliminary subcutaneous injection. Both methods of procedure are described by the makers of the serum, who state that favourable results have been obtained in America from its use. It has long been recognised that the intoxication symptoms in lobar pneumonia are frequently out of all proportion to the extent of the pulmonary involvement. The degree of pyrexia, the distressing insomnia, the dangerous cardiac failure are all suggestive of a toxæmia, and it is quite conceivable that good might result from the use of a neutralising anti-serum, given with the object of assisting the patient until from his own tissues the protective bodies have been elaborated.

2. These agglutinating sera for use in type diagnosis are issued in phials of 1 c.cm. with full instructions as to the technique required for their use. The mouse method could hardly be pursued by a practitioner unless he had a licence for vivisection, but for the culture-tube method the provision of a suitable nutrient broth would be a not unsurmountable difficulty.

IRISH WHISKY.

(DUNVILLE AND CO., LTD., BELFAST.)

Two samples of whisky have been submitted to us for analysis, one being described as "Fine Old Whisky V.R.," and the other as "Special Liqueur." The following analytical data were obtained :—

	V.R.	Liqueur.
Proof spirit, per cent... ..	70·4 ..	71·3
Total extractives, per cent. ..	0·039 ..	0·1
Mineral matter, per cent. ..	0·009 ..	0·005
Organic extractives, per cent.	0·03 ..	0·095
	Parts per 100,000 of absolute alcohol.	
Secondary constituents :—		
Volatile acid (acetic) ..	11·75 ..	16·0
Furfural	2·0 ..	1·1
Esters	6·1 ..	5·1

A general consideration of these figures shows that the liqueur brand is a pot-still whisky and the V.R. probably a blend. This is borne out by the slightly higher aldehyde content of the liqueur whisky, whilst the relatively high volatile acidity in both samples is evidence of a proper degree of maturation. Both are free from acrid flavour, the liqueur brand being particularly smooth, pleasant, and characteristic of the highest grades of Irish whisky, whilst the V.R. maintains the odour and flavour associated with this brand. The deleterious qualities associated with the presence of furfural are practically non-existent, as indicated by the small trace of this compound present. These whiskies were analysed by us in 1908 and 1914, and in spite of the lower alcohol content now enforced there is no falling-off in their good qualities.

QUININE ETHYL CARBONATE (EUQUININE) AND DIQUININE CARBONATE (ARISTOCHIN).

(CHEMICALS AND BY-PRODUCTS, LTD., THE COOPER LABORATORY, WATFORD.)

We have received specimens of these two quinine derivatives. The quinine ethyl carbonate is of good appearance, tasteless, and melts between 92° and 94° C. It is a pure and high-class preparation. The diquinine carbonate, or "aristochin," is colourless, tasteless, and melts at 183–4° C. It gives, however, a positive chlorine reaction, and analysis shows it to contain 6·9 per cent. of chlorine; the product cannot therefore simply be carbonate of diquinine. In a previous issue (June 18th) we stated that the S. H. M. Co. were the sole makers of quinine ethyl carbonate in this country. Chemicals and By-Products, Ltd., inform us that this is not correct, as they have made this quinine salt for the past two years.

TAWNY PORT.

(CHAS. TUCKEY AND CO., LTD., 3, MINCING LANE, LONDON, E.C.3.)

When analysed this wine was found to have the composition—

Alcohol	19·3	per cent.
(equivalent to 33·6 per cent. proof spirit)		
Total extractives	8·6	per cent.
Containing mineral matter	0·22	,,
,, sugars	7·6	,,
Fixed acidity (tartaric)	0·41	,,
Volatile acidity (acetic)	0·05	,,

The sugars consist of a mixture of dextrose and lævulose, the latter predominating. Cane sugar is absent. These analytical figures support the opinion that this is a well-made and sound wine, conforming to the type of a good port.

NUVITA DIETETIC BISCUITS.

(GEORGE HERBERT, LTD., GLASGOW.)

Each biscuit weighs 6·5 g., and is divided into two portions of approximately equal weight; the bottom part consists of ordinary biscuit material and above it is superimposed a light-brown, very sweet layer of a thick, slightly pasty consistency. Each biscuit is wrapped in silver paper and when eaten is agreeable to the palate. The two portions were examined separately. As might be anticipated, there is no evidence of the bottom (baked) portion possessing any enzymic activity; the top, however, has a slight liquefying action on starch paste and converts a portion of this starch into sugar. It would appear to consist of a diastatic preparation mixed with wheat flour and some dead yeast cells. The manufacturers claim that the "active" or top layer is composed of materials containing vitamins natural to the wheat berry and also those added from another source. The biscuits are stated to be suitable for convalescents and others of weak digestion. Care and thought appear to have been directed to the manufacture of these biscuits, which are novel in character, and if the claims are substantiated they may be useful in a number of conditions.

ONE of the two offices of Master of Lunacy having been rendered vacant by the death of Sir David Brynmor-Jones, the Lord Chancellor has decided to act on the recommendation of the Royal Commission on the Legal Departments with reference to the suppression of one mastership, and no new appointment will be made.

random, but we can forgive anyone who after reading them abandons dermatology in despair.

In Part 1, which deals with methods of treatment, X rays are given first place, and Dr. Sibley claims that "there are but few dermatological lesions which are not improved or cured with skilled treatment by the X rays." He apparently employs them even for dhobie itch. Apart from X rays, methods of treatment by radium, electrolysis, ionisation, high-frequency currents, vaccines, carbon-dioxide snow, hyperæmia, and baths are described. The great value of diathermy is rightly insisted on. To treat scabies "with radiant heat associated with sulphur inunctions" is perhaps carrying "modern" methods a little too far. In Part 2 the various diseases of the skin are dealt with in alphabetical order, and usually a number of alternative methods of treatment, some of them not very helpful, are given. The detailed description of a definite line of treatment of proved value, based as far as possible on an intelligent appreciation of the ætiology of the particular disease under consideration, would have been more useful to the student of dermatology than a list of methods which "may be beneficial," or "have been used." We read that "high-frequency currents have been tried" for lipoma and that "painting the tumour with liquor sodii ethylatis for two or three days might be of service in some cases." It might—but then again, it might not.

A number of very good photographs are included. Some of them illustrate the effect of treatment in such conditions as acne, alopecia, seborrhœa, and scarring. Advanced students will be interested in the excellent photographs of rare cases that have been under Dr. Sibley's care. It is a bold effort to attempt a manual mainly concerned with treatment in dermatology, especially as, in the author's opinion, the ætiology of so many skin diseases is obscure and their treatment therefore mainly empirical. The fact that Dr. Sibley's book has run into three editions shows that his endeavours have received a fair measure of appreciation.

INSANITY.

Manic-Depressive Insanity and Paranoia. By Prof. EMIL KRAEPELIN. Translated by R. MARY BARCLAY, M.B. Edited by GEORGE M. ROBERTSON, M.D. Edinburgh: E. and S. Livingstone. 1921. Pp. 280. 21s.

THIS is a translation from the eighth German edition of the "Text-book of Psychiatry," Vols. III. and IV. The larger part of the book is devoted to the development of Prof. Kraepelin's well-known conception of the merging of mania and melancholia in a single definite form of mental disorder. After the separation of exhaustion and toxic states from mania and their clinical description as confusional insanity, the occurrence of cases of true mania seemed to many observers to become rare. In this work, however, descriptions of mania are again including such disorders of perception, consciousness, and memory as are reminiscent of confusional states. At times a suspicion is roused that it is in fact toxic and exhaustion states in their very varying aspects that are being described. However, Prof. Kraepelin's case is a good one and is presented in a masterly fashion. His analysis of the temporal dissociation of symptoms affecting intellect, emotion, and volition during the course of a case of manic-depressive insanity is exceedingly interesting if not wholly convincing. Dr. Mary Barclay's translation is good, though very obviously from the German.

Lunacy in India. By A. W. OVERBECK-WRIGHT, M.D., Major, I.M.S. London: Baillière, Tindall, and Cox. 1921. Pp. 406. 21s.

THE general account of the various mental affections regarded from the psychological, pathological, and clinical aspects as they occur in India given by Major Overbeck-Wright is not very notably different from accounts of similar affections occurring in Europe. His classification is founded upon that of Dr. Lewis C. Bruce, and mania, melancholia, and delusional insanity are treated of as insanities of toxic origin. Descriptions of symptoms and treatment are lucid and adequate. Probably the most useful chapters are the medico-legal ones, and these alone should render the book of value to practitioners in India.

SURGICAL WARD WORK AND NURSING.

Fourth edition. By ALEXANDER MILES, M.D., F.R.C.S. Edin. London: The Scientific Press, Ltd. 1921. Pp. 418. 10s. 6d.

THIS handy-sized volume, now appearing in a fourth edition, is a useful and concise compendium for a nurse to read and refer to during her training, and whilst working in a surgical ward. It covers the whole field of knowledge required by the surgical nurse, though some parts are more thoroughly dealt with than others. The information is up to date and for the most part judiciously selected. 393 illustrations are included. Since it is likely that further editions will be called we note a few errors and omissions. No mention is made of Irving's apparatus, now so commonly used for draining the bladder. The only form of gastroscope mentioned is a flexible one, though a rigid tube (e.g., that of Hill or Jackson) has for some years been the more common, if not the only, form used. Clover's and Hewitt's inhalers are figured and described, but not named. The segregator devised by Luys is attributed (both in the index and under the illustration on p. 247) to Leaws. On p. 391 are two illustrations of Thomas's knee-splint which are wrongly labelled "Caliper Splint"; to these illustrations we could find no reference in the letterpress. Fig. 377 portrays Jones's elbow-extension splint, but it is described as a "Splint for the forearm." Fig. 348 is neither named nor mentioned in the text. The type of cholecystectomy forceps attributed to Moynihan in Fig. 149 is certainly not the usual form now recommended by him. For treatment of secondary hæmorrhage after excision of the tongue the nurse is told to hook the tongue forwards "so as to compress the arteries against the lower jaw." Surely the efficacy of the method of dragging forward the stump of the tongue does not depend on this.

These minor errors, however, detract but little from the value of the book, which would certainly constitute a useful guide to one designing a course of surgical lectures to nurses.

THE ELEMENTS OF VEGETABLE HISTOLOGY.

By C. W. BALLARD. Associate Professor of Materia Medica, College of Pharmacy, Columbia University. New York: J. Wiley and Sons. 1921. Pp. xiv.+246. 18s.

Vegetable histology is a subject of much importance to students of pharmacognosy and food analysis, and a clear exposition of the fundamental facts and methods is needed by those who are beginning the study of this subject. Mr. Ballard in attempting to produce such an exposition has cut down the subject matter as much as possible so as to avoid the inclusion of numerous confusing details, but has not shown much judgment in his selections of matter. His book is divided into 19 chapters, of which four deal with the microscope and its accessories, and the preparation of material; two other chapters describe the chemical reactions of plant tissues and the use of stains, while the remaining 13 deal with the structure of the various plant organs. In a book of this kind the inclusion of so much matter relating to microscopes and their accessories seems rather out of place, since such information can be better obtained from books on physics or from special works upon the microscope as an instrument. A similar criticism applies to much of the general botanical anatomy of leaves, roots, stems, &c., which can be better learnt from text-books on botany. The illustrations are the subject is a histological section, especially with a magnification approximately equivalent to that given by a ⅙ inch objective and a medium ocular. Many such photographs are published in medical journals and most convey very little information to anyone who is not familiar with the appearances which it is sought to represent. The chief difficulty arises from the fact that the photograph reproduces only a single plane in the section, whereas visual examination is—or ought to be—always accomplished with a twiddling of the fine adjustment which gives a synthetic picture of the many planes into which an ordinary section can be divided. Practically also the absence of colour is a substantial defect, and it is unfortunate that while high-power colour photographs can be easily taken, no technical journal can afford to reproduce them regularly. The main claims that are made in favour of the photomicrograph are two in number. The first is that it reproduces what is actually there. This is illusory in so far as it fails to recognise the possibilities of altering the whole appearance and apparent nature of the details by altering the conditions of illumination, screening, and other technical minutiæ; photographs put forward as proof of the existence of some histological fact are open to the same critical consideration as those which purport to demonstrate the material existence of the spirit. Adequate investigation of microscopical appearances which are in dispute can be made only on the specimens themselves; for these no sort of photograph can be substituted. The second point is that photomicrographs are easy to do. This is undoubtedly true, for it is difficult to avoid getting some sort of result, and first-rate pictures are within the compass of most people. Indeed, the facility with which a process, still holding some of the glamour of the mysterious, can be put through has done much to encourage the "camera fiend" element in our histologists.

The alternative to photographs is drawings. No one can doubt their essential superiority who will compare the illustrations in, e.g., MacCallum's "Pathology," with those in, e.g., Beattie and Dickson's admirable text-book, and set himself to make out what the various black and grey marks on the paper mean. Drawings are commonly thought to be impracticable because of the time and artistic skill required, and undesirable because the original appearances have been through the uncertain mill of human judgment and interpretation. As a matter of fact, failing the original specimens, what the reader wants to know is, not what is there according to the camera, but what the author thinks is there; in the text we want the author's interpretation of what he has seen and the same is true of his illustrations. Drawings truly take much longer; a fairly elaborate picture may represent a fair day's work. But it is worth very much more than the photograph, so that two or three well-chosen pictures may go further to explain a subject than a dozen or more unintelligible photographs. And the technique of making good drawings is not very difficult to acquire. There is no need to keep a "Professor of Art as applied to Medicine," as is done at Johns Hopkins. It is not derogatory to the dexterity of Dr. E. H. Kettle, Dr. G. W. Nicholson, and Mr. G. A. Pannett to hope that others may emulate them and publish with their papers illustrations from their own drawings which really do illuminate the sections they have cut and the philosophy with which they have examined them. Let us therefore hope that the art of histological drawing will find more adherents, and that photomicrography may be relegated to its useful sphere—say, of reproducing appearances under quite low magnifications, where the labour of a drawing may become immense, or of picturing bacteria, blood corpuscles, and other objects with a negligible thickness and definite outlines.

◆

The Objective Study of Neurosis.

The subject selected by Dr. F. L. Golla for his Croonian lectures before the Royal College of Physicians of London, three of which have been published in recent issues of The Lancet and the fourth in the present issue, is one which must make a direct appeal to all who desire insight into the significance of that much-misused epithet "neurotic." Too often the physician is compelled to mask his ignorance of the precise nature of a patient's affection by relegating it to the ill-defined and ill-demarcated group of "neurosis," and notwithstanding the immense strides that have been made in neurological and psychological diagnosis exploration of the objective aspect of functional nervous disease has certainly not proceeded pari passu with that of the subjective. For the moment, indeed, such nervous disorder as is apparently sine materie has been passing to some extent into the hands of the practising psychologist and the professional psychotherapist, whose argument that psychological disease should be cured by psychological methods is perfectly legitimate and whose therapeutic successes are, at least in many instances, as striking as any obtained in other fields of medicine. Dr. Golla, it will be seen, approaches his subject exclusively from the physiological standpoint, and deserves every credit for his bold endeavour to call a halt to the rush of purely psychological investigations with which the study of neurosis is like to be inundated. If we understand his position rightly, he would have it that the abnormal psychical reactions of the neurotic are themselves but symptoms, and are not the cause of anything but rather the result of something. That something is "a physical disturbance of mechanism," constituting the primary factor in the neuroses; a physical disability, a "failure of organic equilibrium" is the cause of the neuropathic condition and the necessary precedent to its manifestations.

There is, of course, no actual novelty in the contention. For that matter we have been told recently by Freud himself that "the structure of psycho-analysis that we have erected is really only a superstructure which at some future time must be placed upon its organic foundation, but what this is we do not know as yet." Relying to a considerable extent on war experiences, the controversies arising out of which are evidently far from being at an end, Dr. Golla stresses the point that exposure to similar if not identical conditions has never resulted in the development of neurosis in all thus exposed; not all, who would, can or will become hysteric, neurasthenic, or whatever it be. Patently some other factor enters into the matter. The physician who believes in the psychogenic origin of the major part of the neuroses of war also admits the existence of an antecedent element, constituted by a specific hereditary predisposition; and yet this will not engender a neurosis in a given case of difficulty of adjustment to war conditions unless and until, as has been frequently emphasised, the unconscious motive or motives to which weighty psychological import is assigned have revived and reinforced wishes that have been repressed in older, pre-war, unresolved conflicts. There may, indeed, be little evidence of any specific hereditary predisposition, though Dr. J. M. Wolfsohn, working with Sir Frederick Mott, obtained a history of family or individual neurosis in a very high percentage of all war neurotics, and there may be little proof that anything mental conditions than on the amount of physical energy expended, is one of no little importance and of hope. Physical exercise is necessary in industrial work, and cannot well be avoided; environmental conditions, on the other hand, are capable of amelioration.—Dr. Alice Hamilton contributes in the May number an excellent summary and discussion of the position relating to malignant tumours of the bladder among aniline workers. The summary of evidence is a valuable one, and the case put forward for considering that arsenide of hydrogen may be the substance at fault is of interest. The case would be stronger if evidence was forthcoming that operatives exposed to arsenide of hydrogen in other industries, apart from the dye industry, suffered in the same way. Much more light is needed on this subject; just as it is upon the occurrence of cancer among chimney sweeps, briquette makers, and smokers, all of whom are exposed to products of distillation of vegetable matter. Some substance or substances are present which seem to possess the power of sensitising the tissues to malignant growth. More definite information might help to elucidate the whole obscure problem of malignancy.—Two articles dealing with poisons which may cause toxic jaundice have appeared: one in the May issue, by Dr. D. C. Parmenter, is concerned with tetrachlorethane poisoning as seen in an American plant making artificial silk, in which this volatile hydrocarbon is used as a solvent for cellulose. Exposure to fumes seems to have been well controlled, so that no fatalities or serious cases of jaundice have occurred, but a number of cases of minor illnesses are reported. Abnormal fatigue, discontent, general nervousness, loss of appetite and sleep, are the early symptoms reported, while later nausea and sickness, with abdominal pains and possible jaundice, may occur. Blood abnormalities were always found to be present, including (1) an increase, up to 40 per cent., of large mononuclear cells; (2) a slight elevation of the white count; (3) progressive but slight anæmia; and (4) slight increase in platelets. The presence of a considerable number of young mononuclears distinguished the severer cases. Dr. Parmenter holds that if sufficient care is taken to remove by suction draughts the fumes of tetrachlorethane, and if careful medical supervision is instituted, the use of tetrachlorethane commercially is feasible without undue risk to the workers; he lays considerable stress upon the importance of blood examinations for detecting early cases. The second article deals with T.N.T. poisoning, and is referred to elsewhere in these columns.

Wiener Archiv für Innere Medizin. Edited by W. FALTA and K. F. WENCKEBACH. Vol. II., Part 3. Pp. 357–633. June 30th, 1921. Berlin: Urban and Schwarzenberg. M.102.—Osteoarthropathy in Carcinoma of the Lung, by Priv.-Doz. Dr. Maximilian Weinberger. A full clinical and post-mortem report is given of a male patient, aged 62, in whom symptoms due to the bone changes of osteoarthropathy developed nearly two years before the clinical signs of disease of the lung (primary bronchial carcinoma) were evident. The bone changes were so widespread and the enlargement of the extremities so marked that the patient was admitted to hospital with the tentative diagnosis of acromegaly. Skiagrams of the forearm and knee, and a photograph of the femur after its removal on post-mortem examination complete the communication.—Acquired Hæmolytic Jaundice (Widal-Abrami), by Priv.-Doz. Dr. Hans Pollitzer, Drs. Hans Haumeder and Stefan Schablin. The pathogenesis of acholuric jaundice and the relation of the acquired to the familial or congenital forms is discussed at length. Illustrative cases are given, and in two of these the diagnosis is made in the absence of an increased fragility of the red blood corpuscles. The authors give their reasons for the view that the disease is due to dysfunction of the spleen.—Vascular Spasm in Intermittent Claudication and Reference to Certain Capillaromotor Phenomena, by Priv.-Doz. Emil Zak. The author demonstrates the important symptoms of intermittent claudication in the normal upper extremity by depriving the limb of its blood-supply by pressure on the brachial artery simultaneously rapidly clenching and unclenching the fist some 30 times. He thus explains the vascular spasm and ischæmia in intermittent claudication as the result of a normal reflex called into action by the deficient supply of blood to the part. The nature of the stimulus that provokes this reflex is discussed, and reference is made to the clinical aspect of recent physiological work on capillary tone.—Contributions to the Clinical and Pathological Study of Tetany, by H. Elias and E. H. Spiegel. The authors find an increased phosphorus content in the blood serum in various types of human tetany. The inorganic phosphorus accounts for this increase in the total, the lipoid phosphorus being unaltered. The increase is generally more marked in severe cases, and it does not appear to be determined by muscular spasm. They maintain that it is an important symptom, and possibly an ætiological factor, in tetany.—Blood Pressure in Diabetes Mellitus, by Dr. K. Hitzenberger. The blood pressure in 97 cases of diabetes was recorded and compared with that of 561 patients suffering from ailments not likely to influence blood pressure. The author found the average blood pressure lower in diabetics under 40 than in the control cases, while in diabetics over this age it was higher than in the control series.—Hæmorrhagic Nephritis and Tuberculin Hypersensitiveness, by Doz. Dr. A. Müller-Deham and Dr. Kuno Kothny. Ten cases of acute nephritis are reported in which von Pirquet's skin reaction was strongly positive. In no case was there any sign of active tuberculosis, but there was clinical evidence of "latent" tuberculosis in all cases. This last statement is based on the presence of impairment of percussion note at the apex or hilus of the lung, or on signs of old pleurisy. The authors claim to have cured six of their patients and improved four by the subcutaneous injection of Koch's old tuberculin and bacillary emulsion. With one exception of 26 weeks' duration, the average duration of illness before admission was 1½ weeks, and the average period of treatment was 2½ months. In the success of the specific therapy they employed they find support for their view that hypersensitiveness to tubercle toxins is an ætiological factor in many cases of acute and chronic nephritis.—On the Pathology of Dyspnœic States, by Priv.-Doz. Dr. Leo Hess. The author gives a clinical account and post-mortem findings in the case of four patients who suffered from heart failure and paroxysms of dyspnœa. As a result of his observations he comes to the conclusion that the dyspnœa in these cases was neither cardiac nor cerebral in origin, but rather due to vascular spasm occurring in the pulmonary circulation.—On the Inter-relation of the Composition of the Blood and Hydrochloric Acid Secretion by the Stomach, by Dr. M. Leist. Observations are made from the point of view of the effect on the blood content of chloride and water of variations in the secretion of gastric juice; and, per contra, the effect on the secretion of gastric juice of variations in the protein and water content of the blood.—On the Nervous Origin of Gastric and Duodenal Ulcer, by Dr. Stylianos Jatrou. It appears that the nervous system is not the cause, but rather a factor in the causation of gastric and duodenal ulceration.—Pathology of the Secretion of Bile, by Dr. Hermann Beth. The author describes a method for the quantitative estimation of bile salts. The contents of the duodenum containing freshly secreted bile are collected by a duodenal tube, and the results given are based on the examination of 21 patients suffering from various diseases of the liver.—On the Pathology of the Lungs (Part II., Cardiac Dyspnœa), by Prof. Hans Eppinger and Dr. Walter Schiller. The carbon dioxide combining power of the blood is taken as the index of its "acidity." The acidity of venous and arterial blood in healthy persons and in patients with heart failure is compared; the observations are

Annotations.

"Ne quid nimis."

SUBMARINE HYGIENE.

The men of the Submarine Service took great and mysterious risks on our behalf, and for their courage we hold them in honour. But in peace-time they still have to face discomforts of which we know little. Perhaps the most persistent is the stuffiness of the boats, which is explained in a handbook for medical officers of Submarine Service, by Surgeon-Commander R. W. B. Hall, R.N., issued by the Admiralty. Stuffiness is due to the presence of the crew and to gases from the batteries and engines. The engines now blow the products of combustion straight overboard, so carbon monoxide is no longer a danger, and the specially susceptible white mouse, the original mascot of the service, and figured on its banners, is no longer its guardian angel From the secondary batteries, while they are being charged, hydrogen is liberated, and, if in quantity, may cause explosion; also, if leakage occur or disaster, and sea-water floods a battery, chlorine is given off, deadly in 1 part to 10,000. But the chief unavoidable impurities arise from the crew, products of respiration or perspiration, emanations from the body, clothing, or food, and tobacco-smoke. The unpleasantnesses are due to heat, moisture, smell, loss of oxygen, increase of carbonic acid, and, rarely now, carbon monoxide. Arseniuretted hydrogen may be present from aforetime carelessness in the preparation and supply of the sulphuric acid and the lead used in the batteries.

When a boat is on the surface she is ventilated through the conning tower, the hatches, and special ventilating shafts, while if under way, a free current of air is drawn into her through all apertures by the suction of the engines, which discharge the used air overboard. During submersion no fresh air can be introduced, and at first reliance is placed on 16-inch traversing table-fans which keep the air of the compartments freely moving and mixing. After some twelve hours the inhabitants will begin to pant and the purifiers must be used to get rid of the increasing carbonic acid, the air being drawn constantly through trays of soda-lime, renewed every four hours. The air then becomes unduly hot and moist and is passed through coolers, which condense the moisture as snow. Generally there are two ventilation systems, one for the torpedo-room and fore-end, the other for the engine-room and the after compartments, each with its own supply and exhaust trunks for use when the vessel is on the surface, and each helping the mixing of air when the vessel is submerged. The battery exhaust is of special importance when recharging is proceeding, and it can be separated entirely from the general ventilation of the boat. The water-closets have air-exhausts to the engine induction system, useful on the surface: but the closets can be used when the vessel is not deeply submerged, for excreta are washed out of the pan, by sea water admitted through a specially guarded inlet, into a pressure-tight chamber, which is then closed to the pan, and the contents are blown into the sea by air pressure of 80 lb. or so. As to diseases, constipation is frequent, and dermatitis from petroleum: the risk of heat-stroke to crews of submarines operating in the tropics is great: eye-strain causes anxiety, it results from long spells at the periscope, but it is understood how needful it is that the observer shall be physically comfortable and have a good seat and a periscope that fits him and suits his sight. Eye-strain depends also in a small degree on the lighting of the boat, for the only light when submerged is electric. Lighting nowadays, to avoid glare, is indirect, the lamps being shielded by metal reflectors which disperse the light over the sides of the vessel painted a "matt" white; there is no enamel paint. Officers and men are very carefully physically selected, the ultimate responsibility apparently resting with the senior medical officer at Fort Blockhouse, the headquarters of the Submarine Service at Portsmouth. Men are not accepted who have suffered from tubercle, pleurisy, asthma, acute rheumatism, or syphilis. Extra and varied food is supplied,

The issue of the book is a return to an old practice of the Naval Medical Department, whereby it sought to teach its own officers by a well-conceived, well-executed handbook. We should like to see included in a later issue tables of the loss by diseases and injuries in the Submarine Service during each of the preceding five years, that medical officers might learn in what directions particular protection might be required.

PRIMARY CARCINOMA OF THE KIDNEY AND URETHRA.

Dr. H. G. Bugbee,[1] of New York, remarks that while hypernephroma is of frequent occurrence, true malignant neoplasm of the kidney is relatively rare. Thus Albarran and Imbert in 1903 found only 13 cases of malignant adenoma out of 529 cases of renal tumour. Among 83 malignant tumours of the kidney operated on at the Mayo Clinic up to July 1st, 1912, only 32, according to Braasch, presented the triad of symptoms characteristic of malignant renal tumour—namely, palpable tumour in the region of the kidney, hæmorrhagic urine, and persistent pain in the region of the tumour, as well as the general symptoms of malignancy. Two of the three symptoms were present in 37 cases, and only one in 14 cases. The clinical diagnosis therefore must often be based only on one or two cardinal symptoms. The conditions most likely to be confused with renal tumour are: (1) "essential" or nephritic hæmaturia; (2) retroperitoneal tumour; (3) bilateral cystic kidney; and (4) closed pyonephrosis. In the great majority of cases a pyelogram clears up the diagnosis. Carcinoma of the kidney, of which Dr. Bugbee records an example, is a distinct pathological entity to be differentiated from hypernephroma. His patient was a man, aged 44, who had had a sharp attack of left renal colic in 1892, but did not pass a stone. About 12 years later he had another attack, after which his urine became claret-coloured after riding on horseback, but he had no colic or other urinary symptoms. He remained well till October, 1918, when he had a severe attack of influenza, and two weeks after the onset developed profuse hæmaturia, and pain and tenderness in the left upper quadrant and left lumbar region. Later frequent and urgent micturition was noted, and a mass became palpable in the left upper abdomen. There were profound anæmia and marked prostration. The urine was thick with blood and pus. X rays revealed a large oval calculus in the left ureter 25 cm. from the bladder. A pyelogram showed that the renal pelvic outline was destroyed. The pre-operative diagnosis was impacted ureteral calculus and pyonephrosis. At the operation a mass of blood clot and pus was found surrounding the kidney which appeared to be gangrenous. Death took place six months later. Examination of the renal tumour showed that it was a medullary carcinoma.

Primary carcinoma of the urethra is so rare a condition both in the male and the female that considerable interest attaches to a simultaneous article by Dr. Richard F. O'Neil,[1] of the Massachusetts General Hospital, who records two cases in a man and woman respectively, together with a review of the literature. Primary carcinoma of the male urethra, of which Dr. O'Neil has collected 58 cases, rarely occurs before the age of 50. Predisposing causes include trauma and leukoplakia, resulting from chronic irritation. Stricture is present in more than 50 per cent. In some cases there is no venereal history whatever. In the majority of cases the lesion arises from the bulbous portion of the urethra, but Peacock and Menard have each reported cases in which the disease began in

THE LANCET.

LONDON: SATURDAY, AUGUST 20, 1921.

The Famine in Russia: An International Menace.

The terrible conditions of disease and death associated with the famine in Russia have been made known to everyone through the whole press of Europe, and the menace to international health, which is clearly indicated, has led to many questions as to what methods, if any, of control are being employed. In particular those unaware of the present position of the League of Nations inquire why some international health bureau, under the League, is not able to bring the coöperative power of medicine to bear upon the evil. Alas, the answer to this question is as easy as it is painful to give. The international bureau of the League is not as yet instituted; constituent powers may be able to use some of the machinery and resources of the League in the fight against disease, but the full power of international coöperation is wanting. An admirable scheme for an International Health Office of the League was laid before an international health conference in London 18 months ago, and was adopted last December by the Assembly of the League, but the organisation designed has never been able to secure existence. The scheme, it may be remembered, proposed the setting up of an international health office, under the League of Nations, to consist at the outset of delegates appointed by all the Governments represented on the Committee of the Office International d'Hygiène Publique, and by other powers, not co-signatories of the Office International but adherents of the League, with a competent executive. If this scheme had materialised a fine vista of international health would have been opened, medicine taking its place as the one great thing whose international character can never be disputed. The necessary unity of design and purpose was, however, absent; the scheme has not matured, and the attitude of the Government of the United States towards the League of Nations makes perseverance in this direction for the time useless. Meanwhile, when confronted with so great and pressing an international problem as the organisation, erection, and maintenance of a sanitary cordon on the Russian frontiers, the League has only been able to give partial assistance by means of an Epidemic Commission maintained, in the name of the League, by the voluntary contributions of a certain number of Governments. This Commission, though it has done excellent work within the limits of its resources, has now nearly exhausted the relatively small amount of money and material which has been placed at its disposal by these Governments, and by the central Red Cross agencies.

The Imperial War Relief Fund issued last week a moving appeal to the nation for subscriptions to the Russian Famine Relief Fund, and in a few eloquent sentences presented to the public a picture of terror and misery unparalleled in the history of the world. The numbers of the starving population, estimated at ten millions, make relief appear hopeless, but money must be sent to save what can be saved. From this appeal we learn that once again, as the miserable wandering masses move and scatter, there is the risk that they will carry with them the epidemics that follow hunger, and the diseases which are known to be present among them. Coincidently with this great disturbance of population and spread of infection is a stream of western migration, due to the hastening out of Russia of the large masses of non-Russian populations—particularly Polish—which are now arriving or expected on different parts of the frontier from Riga to the Bosphorus. It is against this risk that the nations of Europe must help themselves and must make what individual and coöperative efforts they can. Warsaw should be one of their principal objectives, as it is to or through Poland that infection is most likely to be carried. Now much can be done in Poland. Dr. Norman White, Chief Commissioner of the League of Nations for Epidemic Diseases, has recently paid, in the company of competent international advisers, a visit to Warsaw, and is able to report that the Government of Poland is taking vigorous steps to succour the immigrants and to protect their own country and the rest of Europe from mass infections. The gates of entry are not numerous and can be watched, if adequate assistance is given to the local machinery. The Polish Government has had a sad experience in face of disease and has learned the lesssons well. Just two years ago Poland was visited with serious outbreaks of typhus. At that time a small international committee, formed at the instance of the new League of Red Cross Societies, went out to Poland, and gave advice from the personal experience of a well-chosen personnel on the direct ways to prevent and combat epidemic disease, and there is no doubt that Poland is determined to carry on the sanitary battle in defence of Europe. The Polish health authorities have fought typhus with energy and success, and Warsaw remains an excellent nucleus from which measures for the stay of the epidemic diseases may be put into action. What has been shown to be practicable in Poland should be equally feasible in the other border states of Soviet Russia.

The three diseases most feared are typhus, cholera, and plague, but plague, which requires for its propagation the intermediary assistance of rats, is the least likely to assume epidemic proportions, assuming that we are spared the pneumonic variety. If properly handled, the extension of cholera may be checked as easily as that of typhus, for, while the former disease diagnoses itself so that the patients do not easily escape the sanitary cordon, typhus, with its obscurer manifestations and longer incubation period, may escape detection. All medical eyes are turned anxiously towards Geneva, where measures of relief are being settled, and among them the important question of strengthening sanitary precautions in the border States, particularly by extending the work of the Epidemic Commission of the League of Nations. All countries should do what they can to find money and men to organise something in the nature of international effort against an international menace. Moreover, should infection spread, it is the bounden duty of all nations to recognise the liability of their conventions to make international notification of their outbreaks of disease. There must be no more concealment such as has taken place, for example, at different times at Lisbon, Paris, and Marseilles.

Histological Illustrations.

Within about the last 25 years photomicrographs as illustrations of microscopic objects have come into use, and there is a growing feeling that they are not fulfilling their promise, and that facility of production is leading to their abuse. The objections to them are particularly obvious when

Foulerton puts forward an explanation of this anomaly. Recalling Leathes's work, which showed that the common fatty changes in the liver are due to the accumulation in the cells of that organ of fat brought from the normal fat deposits of the body to be unsaturated and so made ready for immediate use, he suggests that the arsenobenzol compounds are gradually accumulated and stored up in the fat deposits during a course of treatment, and then, owing to some slight variation in the normal course of metabolism, are carried to the liver with the fat in which they are dissolved in such quantities that the liver cells are killed en masse. He points out in this connexion that a considerable number of cases of delayed salvarsan poisoning have occurred in men who have been in hospital for some weeks where rest and an ample diet may be presumed to have led to the accumulation of reserve fat; if such a case returns to a more strenuous life the mobilisation of some of this fat may set free an undesirable quantity of arsenic.

T.N.T. POISONING IN AMERICA.

THE short period during which T.N.T. was extensively used in America afforded no opportunity for exhaustive study of its poisonous effects, but the article by Dr. Alice Hamilton in the July issue of the *Journal of Industrial Hygiene* gives a useful account of American experience in manipulating this high explosive during the war. It summarises reports made by students placed in certain of the factories to make observations; there does not, however, seem to have been in the United States any organised medical supervision of those exposed to risk as was established with success in this country. Contrary to early English experience, the handling of pure T.N.T. seems to have been harmless compared with handling amatol, a mixture of T.N.T. with the hygroscopic salt, ammonium nitrate. The skin as a portal of entry was recognised to be of overwhelming importance, while oily substances favoured absorption. No evidence, from observing negroes, could be obtained of any racial immunity. Most of those employed were men, hence a comparison of the susceptibility of men and women could not be established. Younger men were found to be more susceptible than older men, to an extent which justifies the statement that it seems poor economy to employ them. Just as in England, those within the first three months of employment were found to be those most liable to the poison. No evidence was found to establish the conclusion that crude T.N.T. was more poisonous than pure T.N.T. or vice versa, but crude T.N.T. was more productive of dermatitis. The Webster reaction, which was brought out in this country, was found to be a trustworthy test for the absorption of T.N.T., but not of impending toxæmia, since the test frequently becomes negative in severe cases, probably due to the elimination of T.N.T. being suspended in such cases.

ENDOCRINE BALANCE.

INCREASE in our knowledge of the effect of the internal secretions has provided physicians with valuable methods of treatment; but there is to-day a danger that the treatment will outstrip the knowledge and that enthusiasts will pin their faith much too largely upon glandular therapy. Harvey Cushing in a paper on the "Disorders of the Pituitary Gland,"[1] has laid special stress upon this danger. After mentioning the enormous amount of literature which has arisen upon the subject in recent years, he gives quotations from different papers, showing to what extremes such therapy has been carried. There is one quotation especially that deserves repeating. It is, that "in diagnosis it is no longer a question of bimanual examination, of listening to the lungs, to the heart, testing the blood-pressure, examining the urine, examining the blood. .... It is a matter of observation and also of tests to determine what the endocrines have been doing to a patient before she comes to us ....." English surgeons will be conversant with similar extreme views which have been put forward in this country. We may recall a suggestion made at a recent discussion in London that the treatment of Graves's disease consisted solely in administering the correct glandular extract. Long articles containing misleading statements have appeared in the lay press on the value of thyroid and other glandular extracts. Such statements are usually put forward without any adequate proof and too often are based only upon attractive though fantastic theories. The danger of such views is two-fold. Firstly, there is the fact that the extracts are widely advertised by their makers and are often sold by chemists without any restriction, so that they may be taken in sufficiently large quantities to give rise to dangerous symptoms. In this respect it is only necessary to mention the ill-effects that may follow the administration of large doses of thyroid extract. In the second place, certain symptoms may be wrongly interpreted and extracts may be administered without any attempt being made to determine the cause of the symptoms. When extreme claims are made for the value of such extracts by qualified medical men the danger becomes very great indeed. Cushing, in his paper, has taken as the basis of his remarks the disorders of the pituitary gland. He has carefully reviewed the symptoms which are caused by disorders of this organ and has shown how they may be treated; but he also points out how very little evidence there is at present at hand to show that the administration of extracts of this gland are of any real value. He lays stress upon the need for those who would pursue the subject in the proper spirit to keep an exact almanac of results, so that they may be able to avoid unfavourable winds, currents and counter-currents, and may discountenance the exploitation of the few discoveries that have already been made.

BLOOD SUGAR REGULATION.

IN a recent issue of the *Journal of Biological Chemistry* (1921, vol. xlvi., p. 381) E. Langfeldt gives a useful historical survey of investigations on sugar regulation before recording the results of his own experimental work. Bernard supposed that blood sugar was secreted by the liver, and that this secretion was regulated by the nervous system. By a nerve path via the medulla oblongata the liver received impulses to increase sugar secretion, and thus the blood was supplied with sugar in proportion to the requirement. On this theory Bernard regarded diabetes as a nervous disease. Von Noorden introduced a change in this theory; he assumed, with Bernard, that the transformation of glycogen into glucose was governed by the sugar requirements of the organs, but supposed that the transformation resulted from a chemical stimulus brought from the muscles to the liver. Bernard supposed that the diastase found by him might be an important factor in the process, but it was not clear how glycogen and diastase could exist in the same cell without immediate glucose hydrolysis. Bang suggested that pure liver diastase is inactive and that an activator is necessary; that by the secretion of bile the liver cells absorb and secrete sodium chloride, which activates the diastase and maintains normal blood sugar regulation. The mechanism of adrenalin hyperglycæmia, according to Bang, is established in the same way. Grode and Lesser, however, suggest that the glycogen and diastase exist separately in the same cell, but come in contact under certain influences. In the opinion of the author these views are incomplete in that they do not account for both glycogen hydrolysis and glycogen formation, both of which participate in blood sugar regulation. From a critical examination of the literature the author concludes that the pancreas is essential for glycogen formation in the liver.

In researches made on alimentary hyperglycæmia in normal dogs the author found that the blood sugar rapidly fell under normal conditions, it was not else than the current difficulty is at the bottom of the functional disorder. However this may be, for want of a better term, the psychologist accepts the "constitutional" factor in such cases, and if the percentage of neurosis among the combatants in the war was not notably higher than among the civil population in times of peace, war strain is in a sense negligible compared with this pre-existing constitutional inability to deal with psychical conflict. For Dr. Golla it is an "organic disability," so apparent that the medical observer should have found little difficulty in spotting the future cases of neurosis before ever a shot was fired. A praiseworthy attempt was made by the American Army medical authorities to weed out presumptive neurotics during their recruiting days by resort to an expert psychological and physical examination and not a few misfits were duly eliminated, but if Dr. Golla's views are corroborated we should have at our disposal a means of detection which is bound to result in greater military efficiency if it can be employed.

---

[1] Disorders of the Pituitary Gland, Retrospective and Prophetic, Presidential Address before the Association for the Study of Internal Secretions. Boston, June [illegible]th, 1921.

When we turn to consider the evidence adduced for the reality of this organic disequilibrium and the forms in which it expresses itself we confess to a certain feeling of disappointment, though the difficulties in the way of reaching practical conclusions are considerable, and much that Dr. Golla advances by way of experimental illustration is peculiarly suggestive. Micro-chemical changes in nerve-cells, possible evidence of defective oxidation processes in them, are believed to be the underlying physical basis of nervous asthenia, which is a common symptom in some of the neuroses. In another group associated with signs of overaction of the thyroid gland the mechanism of emotion is hyperexcitable as evidenced by the behaviour of the galvanic reflex, the rate of basal metabolism is increased, and the sympathetic system can be shown to be over-irritable. Another type of neurosis is distinguished by the ill-adaptation of primitive instincts and conditioned reflex-patterns or habits to the environment of the individual. Hysteria, again, is according to Dr. Golla a variety of neurosis characterised not by hyperexcitability but by subnormal activity of the affective mechanism, as revealed by galvanic reflex tests. To this last considerable importance is attached, and an ingenious theory of the nature and ætiology is adumbrated, rather than worked out, depending on the objective fact of absence or diminution of the galvanic reflex in response to stimuli of an affective order. It ought to be mentioned, however, that Prideaux not only found normal reactions in cases of hysteria, but also took records of the galvanic reflex in certain individuals in the normal state and under hypnosis and obtained no appreciable modifications in the reflex as between the two.

Assuming, or accepting, the reality of the objective physiological findings so patiently and ably determined by Dr. Golla, are we thereby any nearer the solution of the problem? Do alterations in neuroglandular mechanisms, in muscle tone, and in galvanic response, in affective reaction and nerve-cell oxidation, afford proof of the physicogenic as opposed to the psychogenic derivation of hysteria and nervous asthenia, of anxiety neurosis and compulsion neurosis? Are we any the more sure that neurotic symptomatology cannot ever be caused by intrapsychical conflict and by unconscious motive? The value of the researches of Dr. Golla resides less in the conclusions tentatively advanced than in the orientation they exhibit towards a sorely neglected side of practical medicine, that of the objective examination of the sufferer from functional nervous disease, and the application to his condition of the resources of the physiological laboratory. To this topic, which is bound to augment steadily in importance, the Croonian lectures of 1921 form a noteworthy contribution. Dr. Golla cites apparently with approval the view of Ribot, that no one really has pleasure in work itself; to its accomplishment only do we look forward with pleasure. The sensory presentation of the bodily activities accompanying effort, we are told, is a "disagreeable feeling" which we do our best to allay by accomplishing the specific action demanded. But there is much to be said, none the less, for the view of one who was no flâneur in his own sphere of activity, that "to travel hopefully is a better thing than to arrive, and the true success is to labour."

◆

HEALTH SERVICES IN WALES.

The second report of the Welsh Consultative Council of the Ministry of Health has been presented to Parliament. It deals comprehensively with a scheme for the systematised provision of health services in Wales. The establishment is recommended of a National Health Institute of Wales at Cardiff, with four Central Health Institutes at Bangor, Wrexham, Swansea, and Newport, and 59 Local Health Institutes at suitable centres. For thinly-populated areas it suggests that in lieu of local institutes there should be small subsidiary hospitals or centres for clinics, with single clinics, these to consist, perhaps, of not more than two beds in very sparsely populated districts. The report further considers in detail existing hospital accommodation in Wales, and finds this to be inadequate for the residential treatment of persons suffering from non-infectious disease, other than mental disease and tuberculosis. How short the accommodation is estimated to be may be judged by the recommendation of an increase of beds of from 50 to 75 per cent. In addition to convalescent homes, of which there are 11 in existence, the report advocates the institution of rest, or holiday, homes for workers run down in health. Better provision of institutions for mental deficiency and for the training of cripples is found to be needed. The provision of full-time specialists for certain diseases, and of consultants to be available in other cases when required, is approved.

Part II. of the report is devoted to the problem of the form of local government which should be established for the administration of the health scheme advocated, and for doing away with the complexity arising from too many authorities interested in health and from too small units of administration. The scheme is capable of effecting much that is highly to be desired, and to be one susceptible of improvement, when once it has been set in motion and when experience has shown where it is defective. It is, however, impossible to ignore at the present time the necessary demand for national economy, and the unwillingness of the community to increase the burden of taxes and rates already imposed upon it. Therefore it would appear that a national supervising local authority is likely to find a large sphere of usefulness in Wales in bringing about improved health service by better administrative methods, and by utilising existing institutions, the services of existing officials, and the services of voluntary workers to the fullest extent. It is not possible to predict or even to advocate immediate, wide-reaching, and costly development, either in the direction of new institutions or of an increased paid service of administrators. To effect a better service without considerable increase of outlay would commend a well-organised health authority to the public it served. To increase the liability of those who have to find the money would arouse hostility and be destructive to efficiency. It seems clear that in all health schemes gradual and considered development, rather than costly and spectacular innovation, will have to be a necessary policy for many years to come, and that anything in the nature of costly experiment on a large scale must be avoided.

THE COURSE OF SUMMER DIARRHŒA IN LONDON, 1856–1920.

By JOHN BROWNLEE, M.D., D.Sc.,
DIRECTOR OF STATISTICS, MEDICAL RESEARCH COUNCIL.

A GOOD deal of work has been done in the Statistical Department of the Medical Research Council during the last year on the question of the relationship of weather to summer diarrhœa. This is not yet completed, but a short synopsis of what has been done is given here.

It has, of course, long been known that epidemic diarrhœa is a disease associated with warm summers, and in the report of the Local Government Board published in 1885 Dr. E. Ballard stated that when the underground temperature at the depth of four feet rises to 56°F. summer diarrhœa begins. This observation is roughly true, but in the work we have done it has not been found that the relationship of summer diarrhœa to the earth temperature is closer than to that of the air. In consequence the following remarks are based solely upon the temperature of the air. It has long been my opinion that summer diarrhœa was in the main (for its ætiology must be multiple) not one disease but two, the epidemic of the first type having its maximum in late July or early August, and of the second type in September. The forms of the epidemics are different and also the duration, the first having a steep ascent and a rapid decline, the second a more gradual slope throughout.

The first trials sought to eliminate the second epidemic. This was done by assuming that only those deaths which were in excess of certain levels were to be used for statistical purposes. In taking the correlations, therefore, between temperature and deaths from diarrhœa, the figures for no week were used unless at least 75 deaths from diarrhœa occurred. The sums of the number of cases above this level were first ascertained. The next level chosen was 100 deaths per week, the third 125, and the fourth 150. Corresponding excesses of temperature were also calculated. Using the mean weekly temperature as the standard of temperature the excesses during the summer above the successive levels of 56°, 58°, 60° and 62° were summed. The most adequate measure seemed to be a combination of the sum of the weekly excesses of temperature over 60° and the sum of the excesses of the diarrhœa deaths over 100. In this case the correlation is in the neighbourhood of 0·8. It would be thus possible to calculate, if the excess temperature above 60° were known, the amount of diarrhœa to be expected very approximately.

The second series of correlations apply to the rise of the first epidemic. The excesses of temperature over 60° prior to the 28th week in the year were summed, and the number of deaths from diarrhœa registered before the end of the 29th week placed in comparison. Here again a very high correlation was found, the correlation being above 0·8. Thus if we know the number of degrees of temperature in excess to the end of the 28th week, the number of deaths within an error of 20 per cent. could be calculated. When, however, the matter was considered more fully it was discovered that a strange break in the statistics takes place. Up to 1899 the relationships hold very closely; after 1899 a gradual change occurs. Instead of a considerable proportion of the epidemic occurring before the 29th week, after that year it begins uniformly later. In 1900, 1901, 1901, 1905 and 1906, though the epidemic is of very similar form to that experienced before 1899, it occurs later in the year though the excesses of temperature were such as would have given rise to epidemics in previous times earlier in the year. From 1907 the maximum of the epidemic, in place of occurring as a rule about the 30th to the 33rd week, occurs in the 35th to the 40th week, and instead of a large epidemic occurring—except in one year, 1911—the number of deaths is comparatively small. As already remarked, epidemic diarrhœa seems to be a mixture of two diseases. Till 1899 the first was predominant. Before that date the later epidemic was most marked in 1895. In 1907 it became predominant; the only year since 1907 in which the amount of diarrhœa was anything comparable with previous experience was 1911. Even in such a very hot year as 1917 a very small epidemic of summer diarrhœa occurred. In former times the deaths associated with such a temperature as occurred in that year would have been well over 200 a week.

It would seem, therefore, that the first type of diarrhœa has become extinct, or nearly extinct, and that the later type alone survives. Inquiring at the London Health Office, Dr. W. H. Hamer tells me that the by-laws for the cleansing of London came into action in 1893, and that by 1898 London had become a vastly cleaner town. This must account for a part of the change, but there is some other phenomenon in addition. For instance, the excess of temperature in 1884 before the 29th week was on all fours the same as that of 1914, and yet the number of deaths in the 29th week of the former year was about 600 and in the latter only 30, while with a very warm summer the epidemic had its maximum in the 40th week of the year. I therefore think it likely that though there may be a good deal of diarrhœa in London this summer it will be late diarrhœa and not on the same footing as the devastating phenomenon of the last century.

CONTROL OF VENEREAL DISEASES.

CONTINUITY OF TREATMENT.

Two important reports, here summarised, emphasise the fact that if we fail to secure continuity of treatment our venereal diseases scheme is a failure. Dr. E. W. Hope estimates that 60 per cent. of patients in Liverpool fail to continue their treatment until they are free from infection. Dr. F. N. K. Menzies and Colonel L. W. Harrison state that the average failure to complete treatment for the whole of the London clinics cannot be put at less than 30 per cent. and is probably higher. The London report points out obvious defects in the arrangements of the clinics which no doubt in part account for this serious state of affairs. The Liverpool report lays stress on the need for fresh legislation to enforce continuity of treatment, and contains a draft of the proposal of the Liverpool Corporation to this end. Both reports merit close study.

CRITICAL REPORT ON THE L.C.C. SCHEME.

The report on four years' working of the joint venereal diseases scheme for London and the Home Counties from the pen of Colonel Harrison (representing the Ministry of Health) and Dr. Menzies (representing the London County Council) shows that the facilities for treatment at the existing clinics are not adequate, and lays emphasis on the need of coördinating the work of the numerous rescue and preventive societies.

The Developing Scheme.

The scheme came into operation in 1917 and consisted of an arrangement between the counties of London, Bucks, Essex, Herts, Kent, Middlesex, and Surrey, and the county boroughs of Croydon, East and West Ham on the one hand and the principal London hospitals on the other hand, for the establishment of treatment centres, the pathological examination of specimens, and the distribution of salvarsan substitutes. The population to be served by the scheme was nearly 8 millions, of which the L.C.C. was responsible for more than one-half. The hospitals taking part numbered 21 in 1917, and the sum payable for treatment in 1917 was £27,000 and for pathological examination £6500. Since 1917 more hospitals have been included in the scheme and during 1920 the work was carried out by 27 hospitals, the total of grants-in-aid for treatment being £75,475 an for pathological work £15,100. Special developments have been the inclusion of eye hospitals in the scheme, the provision of accomthe penile urethra close to the meatus. The growth spreads along the mucous membrane, destroying it, and invading the corpus spongiosum. Later the periurethral tissue becomes invaded, and abscesses and fistulæ supervene, opening in the perineum, scrotum, pubic region, buttock, or rectum. The growth assumes the type of squamous epithelial cancer. The early symptoms are not characteristic, but are merely those of ordinary urethral stricture, consisting in increasing difficulty and frequency of micturition with or without attacks of acute retention, as well as hæmaturia and a purulent discharge. Later on a swelling appears in the perineum simulating periurethral abscess and infiltration and extravasation of urine. Dr. O'Neil remarks that while the disease is rare, its possibility should always be borne in mind in the presence of an indurated perineal mass in a man over 50, as its recognition has a very important bearing on prognosis and treatment. Primary carcinoma of the female urethra, of which Dr. O'Neil has collected 68 cases, including his own case, is commonest between the ages of 50 and 60, and 60 and 70, though instances have been reported as early as 26 or 27 years of age. The symptoms consist in frequent and painful micturition, hæmaturia, and discharge from the urethra. Retention of urine may occur. Pain is usually a prominent symptom, and may be extreme in some cases. The diagnosis is not usually difficult, especially when the disease is moderately advanced. Syphilis in the primary or secondary stage is to be excluded, as well as simple caruncle or a benign tumour. As regards treatment, a large proportion of the cases both in the male and female have become so advanced when first seen as to be inoperable except by local drainage, or by perineal or suprapubic drainage for the relief of urinary retention. More or less radical excision in some cases has been followed by encouraging results.

THE ACTION OF PILOCARPINE IN CASES OF BRAIN LESION.

Prof. Carlo Besta of the University of Messina, contributes an interesting paper on this somewhat novel subject in the *Riforma Medica* of June 11th. In the course of a series of investigations on the action of certain drugs in cases of lesions of the central nervous system, he experimented with injections of pilocarpine in several patients with head injuries and observed results which apparently have not hitherto been described. In ascending frontal lesions, associated either with simple motor disturbance or with destruction or compression of the contiguous brain structure, there occurred within a few minutes after the injection of 2 centigrammes of pilocarpine hydrochloride, and simultaneously with the onset of sudoral and salivary hypersecretion, muscular tremors and spasms on the side of the body opposite to the cerebral injury, with increase in the tendon and bone reflexes. These phenomena increased rapidly, reaching their maximum intensity in about 20 minutes; in one set of cases they were of a choreo-athetosic type, intermingled with jerking movements, in others, which were the more numerous, there was intense hypertonus with continuous tremor and rapid jerkings. In all cases the reflexes were exaggerated and the rigidity was sometimes so marked that the lower extremity remained in an attitude of extension when the limb was raised by placing the hand under the popliteal space. The clinical picture was modified according to the site of the cortical lesion, the upper extremity being mainly involved if the lower and middle portions of the ascending frontal were implicated, and the lower extremity in damage to the upper portion. This topographic relation, however, was not absolute, and moreover the neck, face, and tongue muscles only exceptionally showed any evident manifestations, perhaps due to the fact that in organic cerebral lesions these muscles normally have a symptomatology less evident than that of the limbs.

The interest of these manifestations, apart from the problem of their pathological mechanism, lies in the fact that they constitute a characteristic sign of lesion of the pyramidal tract; in 200 cases of head injuries in which the injection of pilocarpine was practised several times and always with the same result, they were observed only when the motor zone was injured—that is to say, the ascending frontal and the base of the three frontals—while they were absent in pure lesions of the frontal lobes, the parietal (including the ascending parietal), temporal, and occipital lobes and those of the cerebellum. The results obtained in cases of head injury encourage the hope that also in cases of cerebral lesion from organic disease interesting results may be obtained from a diagnostic point of view. To this end, Prof. Besta directed his attention to cases of hemiplegia and hemiparesis due to organic lesions of the motor tract, and found that, after the injection of pilocarpine, phenomena occurred exactly analogous to those observed in cases of head injury. It was found, moreover, that in capsular or subcortical lesions the phenomena induced were always of a type more exaggerated and diffuse than in pure cortical lesions. It is worthy of notice also that the symptoms were very marked in seven cases of patients suffering from paresis after encephalitis lethargica. In three cases of tumour of the posterior cerebral fossa with symptoms of hemiataxy, adiadocokinesis, &c, injections of pilocarpine produced no appreciable effects in those parts affected by the cerebellar symptoms, but caused typical and elective exaggeration of the pyramidal symptoms on the opposite side. On the other hand, in two cases of Jacksonian epilepsy, due to cysts at the base of the third frontal and in the parietal lobe, the injection of pilocarpine remained inactive. From these facts it appears that the drug acts only when the cortex of the motor zone is directly involved. The explanation of these phenomena is not to be found in the increased secretion of sweat and the cold produced by its evaporation, because they reach their maximum intensity when the sweating is also at its height, and the patients complain of disagreeable heat; further proof of this was afforded in a case of spastic hemiparesis with hemianidrosis in which the pilocarpine caused sudoral hypersecretion on the sound side only, and had no such effect on the paretic side, which all the same exhibited the phenomena of diffuse hypertonus, tremors, spasms, and increased reflexes. Moreover, if the injection of pilocarpine be preceded by that of a quarter of a milligramme of adrenalin, the secretion of sweat is inhibited, while the nervous phenomena remain uninfluenced; sulphate of atropine has the same effect. It appears, then, that this special action of the pilocarpine is independent of that which causes increased sweat secretion, and is probably one of direct action on the central nervous system; but how and where it acts is not possible to say in the present state of our knowledge. There may be here some analogy, however, to the symptoms produced by ether narcosis observed in the subjects of head injuries.

Prof. Besta's observations are interesting from a clinical point of view, since by means of a simple and harmless measure data may be obtained which demonstrate the existence of a lesion of the cortico-motor tract not revealed by ordinary clinical investigation, and of which further research may succeed in locating the exact site. His observations also have a scientific interest: they have apparently not been described previously and demonstrate a sphere of activity in pilocarpine hitherto unsuspected.

DELAYED POISONING BY ARSENOBENZOL COMPOUNDS.

Much interest and a good deal of alarm have been caused these last few years by the occurrence of a number of cases of fatal necrosis of the liver after the administration of salvarsan or its equivalents. One of the most curious points has been that symptoms of illness have frequently not come on till several weeks after the administration of the last dose of a course of treatment. In an interesting article,[1] Dr. A. G. R.

---

[1] Journal of Pathology and Bacteriology, vol. xxiv. (1921), p. 257.

venereal disease is not satisfactory would be to gravely understate the position." Only the fringe of prevention has been touched by the provision at great public expense, and under skilled guidance, of free treatment at each of the leading hospitals in the city. The diseased person may attend if he chooses and for as long as he chooses. The skill and the money expended do unquestionably result in alleviating a great deal of suffering and may to a small extent limit the spread of the disease. But the failure of the system is manifest: 60 per cent. of the patients cease to attend as soon as the grosser symptoms disappear but long before they are free from infection. In stating this Dr. Hope adds that the system of clinics now in vogue in Liverpool is admittedly as good as any in the kingdom. Clearly, he concludes, it is a waste of public money and public effort to give treatment which fails to have results. The public health object of that treatment is not primarily to benefit the individual but to protect the public, and if, because of non-continuance of treatment, the individual remains a source of danger and of infection, we have rank waste of money and of effort.

A specially appointed sub-committee of the Liverpool City Council has prepared for submission to Parliament a series of proposals which have already received the unanimous approval of the municipal authorities and the local medical profession. The aim of the clauses is to secure continuity of treatment till freedom from infection is reached in the case of every person infected with venereal disease. Such an aim involves compulsory removal to and detention in hospital in certain cases and the provision of suitable hospital accommodation for the purpose. Dr. Hope tells us that measures closely in line with these proposals have already been adopted with success in some of the British Dominions and also in the United States of America.

MEDICINE AND THE LAW.

Will-making by the Insane.

A PROBATE action arising out of the will of Joseph Priddle, who died in Camberwell House, Camberwell, was tried recently by Mr. Justice Horridge, two daughters of the deceased claiming probate of a will made by him when a certified inmate of that institution. Three sons asked that the will should be set aside on the ground of the testator's incapacity through insanity and that letters of administration should be granted. The husband of one of the daughters, at that time engaged to her, had taken part in the making of the will, and had employed a solicitor who had taken every precaution, including the obtaining from Dr. F. H. Edwards, medical superintendent of the asylum, of a written certificate that the testator " has been and is now in a condition to express his testamentary desires in a reasonable fashion," that he, Dr. Edwards, had scrutinised the will, and that " there is no reason from a medical standpoint, having in view my special knowledge of the case, why this will should not be quite valid." Mr. Justice Horridge drew attention to the cases of Sivewright *v.* Sivewright (1920, S.C., H.L., 63) and Banks *v.* Goodfellow (1870, L.R., 5 Q.B. 519). In the former Lord Haldane laid down that " the question is simply whether he understands what he is about," and went on to say that in the case of a testator suffering from a delusion which might have affected him in making the will, in order to invalidate it " the delusion must be shown to have been an actual and impelling influence." Mr. Justice Horridge, in pronouncing in favour of the will of Mr. Priddle, under which, as he had already observed, " the daughters received the lion's share of the testator's property," pointed out that the testator clearly suffered from delusions, but that the question was whether he was suffering from a delusion when the will was made. There was no expressed antagonism towards his sons. The evidence of Dr. Edwards showed that there was testamentary capacity. Dr. Edwards did not examine the testator as to any antipathy towards his sons, but there was no evidence of any. In comment attention may be called to the question of antipathy referred to. It had, of course, not been brought to Dr. Edwards's attention that there might be any such feeling. But it is a point which medical men in the same position may well bear in mind. The persons responsible for the certifying of any person as insane may be near relatives whose action he regards with resentment. They may have acted perfectly rightly and in the interest of the person certified, and it would be an undeserved hardship if they should suffer from animosity on his part which may be the result of an insane delusion as to their action.

Hospital Finance and National Insurance.

Lord Burnham's recent sympathetic and practical speech in the House of Lords on hospital finance and the obligations of the Government was fully reported in THE LANCET of July 30th (p. 257). One of his strongest points was undoubtedly made with reference to obtaining by legislation or otherwise contribution to the voluntary hospitals from the surplus funds of the Approved Societies. The hospitals have hitherto had no desire to extract obligatory subscriptions from the societies or from any other source. They came into being as the provision of the benevolent for the needy. Modern developments in medical and social science have, however, brought about totally different conditions. The Insurance Acts have placed the services of the general practitioner within the reach of thousands who rarely or never sought his aid; the hospitals are expected to supplement the work of the general practitioner, and are willing to coöperate with him to secure the desired end, the promotion of the health of the people. They cannot, however, do an increased amount of work upon incomes which have not increased but diminished. It appears to be consistent with good sense and common justice that the representatives of those who benefit by the work done should contribute to pay for it. It is not consistent with justice that those who rightly send their patients to be treated should be paid for their services, and that the hospitals who undertake the resulting obligation to treat should be driven into bankruptcy by so doing. The necessary legislation should be forthcoming.

Drugs to Induce Miscarriage.

A woman named Halle, 33 years of age, was sentenced recently at the Central Criminal Court to five months' imprisonment in the second division for administering to herself drugs in order to procure miscarriage. She had been denounced to the police by an anonymous letter. In passing sentence Mr. Justice Avory pointed out that in such cases the offence was the same whether an instrument was used or drugs taken, and that for a woman to procure abortion on herself was a serious crime. He might have added to this public warning that given in THE LANCET of Jan. 21st, 1899, p. 182, that no drug capable of being used by quacks in compounding their concoctions will be effective to procure miscarriage unless taken in quantities that will endanger life or seriously endanger health. This was published at the time of THE LANCET's campaign against the sinister trade of quack abortionists,[1] which succeeded in banishing their advertisements from the pages of reputable newspapers.

Æsthetic Surgery.

A fine of £20 with £10 10*s.* costs was imposed by Mr. D'Eyncourt at Marylebone police court recently upon C. H. Willie, against whom the Medical Defence Union had obtained a summons for falsely using the title of doctor, implying that he was registered under the Medical Acts. The defendant described himself on a name-plate as " Dr. Willie, specialist," and carried on business as a " practitioner in plastic or æsthetic surgery," professing to remove marks of old age, scars, excreted in the urine, and there seemed no other explanation than that it is deposited as glycogen. In depancreatised dogs the fall of the blood sugar was much less rapid, and the author concludes that the formation of glycogen depends upon the presence of the pancreas hormone. Further experimental work on partially depancreatised dogs showed that an increase in hydrogen ion concentration of the portal veins is able to produce a heavy glycogenolysis, which led the author to investigate the conditions of action of the liver diastase with the following results. The optimum action of liver diastase in the presence of phosphate anions is at pH6.2, and the optimum of the chloride diastase is at pH6.8. When adrenalin is added the optimum is shifted to the alkaline side, the optimum being at pH7.73. Thyroiodine when added alone has no influence on the hydrolysis of glycogen. Simultaneous additions of adrenalin and thyroiodine has a strong effect. Pituitary extract is without effect. From these experimental facts the author concludes that glycogenolysis is governed by the hydrogen ion concentration of the liver cells, that with a constant blood flow and constant temperature glucose is discharged at a constant rate from the liver to the blood; a part of this glucose is utilised by the body, a part stored in the muscles, and the remainder returns to the liver, where it again forms glycogen. Glycogen formation depends upon the presence of the pancreas hormone, the materials being derived from the carbohydrates and proteins of food. It is concluded that glycogen formation and glycogenolysis are consecutive processes. The diastase acts constantly and glycogen formation takes place rapidly. These conclusions are applied by the author to the origin of hyperglycæmias, which may, he assumes, arise in the following ways: (1) by a change of the hydrogen ion concentration of the liver so that the pH is identical with or close to the optimum of the action of diastase in the presence of salts, as influenced by the action of acids on blood sugar concentration; (2) by a displacement of the curve of action of the diastase so that the optimum is close to the hydrogen ion concentration of the tissue, as illustrated by the action of adrenalin; (3) by a deficiency of the pancreas hormone, giving rise to a decreased formation of glycogen, with a resultant excess of sugar in the blood, as in diabetes mellitus and experimental pancreatic diabetes.

---

[1] THE LANCET, 1898, vol. ii., pp. 1570, 1651, 1723, 1807: 1899, vol. i., pp. 182, 327, 717, 855, 908, 1739; vol. ii., pp. 111, 174.

The author finally advanced a simple chemical theory of blood sugar regulation based upon the fact that the action of liver diastase depends on precise hydrogen ion concentrations.

PULSE AND TEMPERATURE.

The possible interaction of pulse-rate and temperature constitutes an interesting and, we believe, hitherto unexplored field; for the commonly observed relation between the increase of rate and the rise of temperature is generally considered to be a common reaction to intoxication. Dr. E. Rist[1] records an interesting case of infection with paratyphoid A bacillus, occurring in a soldier with a tendency to tachycardia. During the febrile stage of this infection he had four attacks of tachycardia, lasting respectively 3½, 2½, 2 days, and 24 hours. It appeared that when the pulse-rate rose to a certain speed (between 80 and 90 per minute) the tachycardia was constantly induced, the rate rising abruptly to between 180 and 200. The somewhat remarkable consequence of this trigger release was an equally abrupt fall in the temperature, so complete as to suggest when it occurred for the first time that the patient was developing peritonitis. The temperature remained almost normal during the tachycardia, rising again as soon as the pulse-rate fell. Dr. Rist, pointing to the modern conception of fever as a result of increased production of heat and noting in this connexion the experiments of Warren Coleman and E. F. du Bois with the Atwater-Rosa calorimeter, explains these phenomena by supposing that the deficient action of the heart, and the consequent slowing of circulation and diminution of circulating blood, so reduced oxidation as to make impossible any extra production of heat. From this quite plausible explanation it is not a long step to the inquiry: What is the normal result of an increased pulse-rate in fever? Is the accompanying pyrexia the direct result of extra oxidation? If so it is easy to understand why the relation 10 per minute increase of pulse-rate for every degree rise of temperature holds with such regularity for almost all fevers, and why it does not hold true in the special case of pneumonia. In Dr. Rist's case the blood pressure was recorded, and was found to fall during the attacks of tachycardia and with the fall in temperature. The assumption generally made that there is in fever some disturbance of thermotaxy must probably be retained, since without such a disturbance the cooling machinery would be normally capable of neutralising the effect of extra heat production.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

During the years of the war the meetings of this society, though not altogether suspended, were greatly diminished in number and were merely formal. During the last two sessions for the years 1919–20 and 1920–21 the usual activities of the society have been resumed. Founded in the year 1872, under the chairmanship of the late Dr. Chadwick, when the old Leeds Medical and Surgical Club came to an end, the society has for long been regarded as the professional centre of the West Riding. The membership now amounts to 296 ordinary members, and the average attendance for some years prior to the war was about 70 to 80. The meetings are held at the General Infirmary at Leeds and this enables a large amount of clinical and pathological work to be brought before the members. About 12 meetings are held each session, and these usually include two evenings specially devoted to the exhibition of cases, and one, which for convenience is held at the medical school, for the discussion of pathological problems.

In 1892, during the presidency of Mr. William Hall of Leeds, the society decided to celebrate its coming of age the following year by instituting an honorary life membership to enable it to do honour to those members who had retired from practice and who in the opinion of the committee had brought credit on the society. The first three on whom this choice fell were Sir T. Clifford Allbutt, Sir James Crichton-Browne, and Mr. C. G. Wheelhouse, all of whom had taken part in the formation of the society. This list has since been enlarged by the addition of Mr. Pridgin Teale, Dr. T. Churton, Dr. Joseph Dobson, Dr. J. E. Eddison, Mr. Charles Richardson, Mr. Edward Ward, and Colonel H. Littlewood. By a happy arrangement, which is for the benefit of both the parties concerned, the medical library of the society and that of the faculty of medicine of the university are amalgamated and lodged at the medical school, which adjoins the infirmary. All the members of the society thus enjoy the use of a really good medical library and reading room. It is the custom to elect as president in alternate years a medical man who is in practice in Leeds and one who practises in one of the other towns in the West Riding. The president for the ensuing session, which opens in October, and which will see the jubilee of the society, is Sir Berkeley Moynihan.

The second annual report (Cmd. 1446) of the Ministry of Health has been issued complete in one cover, appearing several weeks earlier than the similar report of last year. At its price of 2s. Sir Alfred Mond hopes to enlarge the circle of those who buy and read an account of some of the operations of Government which affect most closely their daily lives. We have dealt with the major part of its contents when reviewing the recent report of the chief medical officer to the Ministry.

---

[1] Annales de Médecine, 1921, No. 5, p. 360.

appearance and rapid spread of pellagra. The disease, generally held to be due to eating maize, is therefore appearing in a country where the peasants eat bread made from wheat and corn. Formerly, when Transylvania was a part of Hungary, pellagra was common, and maize was the staple food of the Roumanian peasantry. The maize is rendered unwholesome by modern intensive methods of cultivation, the grain being harvested while still unripe, with the result that putrefaction occurs. An explanation of the appearance of pellagra amongst the wheat-consuming peasants was provided by a noted veterinary surgeon, who maintained that the disease was spread by the consumption of pork, the swine from which the pork was taken having become diseased through being fed on unwholesome maize. In parts of Italy, Lombardy, and Piedmont, especially, and also in Moldowa (Roumania), pellagra is even more common than in Hungary. The Hungarian Government has distributed wheat flour among the indigent inhabitants of Southern Hungary. This year's outbreak of the disease is not severe, although some patients suffer from mental disturbance, which does not yield readily to treatment. Many of the sick recover when supplied with wholesome food.

Excessive Heat in Hungary.

The summer heat this year has been excessive, the midday temperature being as much as 45° Centigrade, the highest figure for 15 years. In addition to the ordinary inconveniences of extremely hot weather, there are also those of scarcity of water, particularly in provincial places where the supply is derived from wells. Rivers are almost dried up, and if the drought continues, pollution of the remaining water and consequent spread of typhoid and dysentery are feared. Several sunstroke cases have been reported in the capital.

Treatment of Nervous Breakdown.

The number of nervous breakdowns consequent upon changed political and economic conditions has been largely increased, and recently the Neurological Section of the Medical Society held a meeting to discuss the treatment of neurasthenia. During the discussion Dr. Frey advised the use of psycho-analysis, and the selection of amusements according to the results of examination. Cards and other indoor games, open-air sport, plays, and conversation on subjects which arouse the patient's interest, frequently have a beneficial effect. Dr. Frey has found visits to friends or complete change of environment valuable. When treating patients in their homes, he has often found it unwise to relieve women of light household duties, or restrict men from moderate exercise. Exercise and occupation (in the sense of pastime) have a disciplinary effect on patients, the curative value of which is not at present sufficiently recognised, but which he believes to be of inestimable value. Careful selection of cases is necessary. If women were taught dress-making, millinery, dairy work, basket-weaving, the lighter forms of wood-carving, drawing, painting and clay modelling; and if men were taught pipe-fitting, pattern-making, mechanical drawing, carpentry, modelling, gardening, stenography, typewriting, painting (signs and frescoes); and if both men and women were to have a choice of work—then Dr. Frey believes our institutions for the treatment of mental diseases would speedily be transformed.

The Suicide-rate in Budapest.

The year 1920 has shown an increased number of suicides committed and attempted for reasons not far to seek. After her defeat in the war, Hungary has lost about half her territory, and more than half of her population: there is very grave trade depression; the change of frontiers has deprived the country of a good part of its industrial markets, and has frequently interfered with family life, whilst the means of communication which remain are difficult to come by, and the getting passports entails much time, trouble, and expense. Even postal communication with the lost territories is uncertain; a letter travelling 10 miles from Hungary into Roumania takes 7 to 14 days, owing to the censorship. Under these conditions it is not to be wondered at that the number of suicides in the past year amounted to 540, 13 per cent. more than in 1919; of these 391 were men, 146 women, and 3 children. The suicides of children are increasing in frequency; the younger of these three was 11, the oldest 14. The causes appeared to be desperation at loss of parents and cruel treatment by employers. The oldest person who killed himself was 90 years, the highest number of suicides was 103 in November and 107 in December.

Campaign to Abolish Brothels.

On July 29th closed the International Congress for the Abolition of White Slave Traffic. A majority of members of the Congress declared that it is most desirable that the keeping of brothels, already abolished in several countries, shall be so treated throughout the world. Mr. Graaf, the Dutch delegate, made the startling statement that in the public brothels of Amsterdam there are imprisoned 72 foreign girls under age. In one of the Amsterdam brothels a printed note was found which contained a list of all the white-slave traders of Europe, together with a list of places where ready markets could be found. The Congress laid special stress upon the necessity of extending protection to coloured women as well as whites, and of carrying the fight against white-slave traffic into the colonies and dependencies of European States.

Emigration of Pharmacists from Budapest.

The slump in the pharmaceutical trade and industry is bitterly felt by chemists' assistants, who are unable to find situations. From 400 to 500 assistants, all holding the diploma of the University of Budapest, have been out of employment for from 6 to 12 months without result. Of these men, 150 assistants have resolved to emigrate, and the first group of 54 has already left for the United States. As the education of Hungarian pharmacists stands at a very high level, it is likely that in America they will find situations without much difficulty.

INDIA.

(FROM OUR OWN CORRESPONDENT.)

PROVINCIALISATION OF MADRAS HEALTH OFFICERS' SERVICE.

MENTION was made in a previous letter regarding the appointment of a Consultative Council of Public Health to enable the Government to maintain touch with non-official opinion concerning general principles of health policy, and particular questions of medical relief, preventive medicine, &c. The second meeting of the Consultative Council was recently held to consider the reports of the five committees of the Council. One of the most important subjects reported on by the Education and Research Committee was that of the provision of trained health officers. In 1913 the Government decided that health officers might, for the time being, be provided for municipal towns whose population exceeded 30,000, and for towns classed as special—e.g., Ootacumund, Coonoor, and Kodaikanal.

As there were 31 such towns, the health service would eventually consist of 31 appointments. As a first instalment Government sanctioned the posting of health officers in 10 of the most important municipalities of the Presidency, but applicants were so scarce that in 1920 only three towns were supplied; several men who had taken up one or other of the available posts had left them, being disgusted with the conditions of service which they were expected to accept. This was doubly unfortunate, for in that year the Madras University had revised its syllabus for the degree of Bachelor of Sanitary Science, bringing it up to the standard of a British D.P.H., and several candidates had taken the degree. The health officers are purely municipal servants with small prospects of promotion and subject to the whims and fancies of modation for pregnant women suffering from syphilis, the provision by the M.A.B. of accommodation for 18 mothers and 30 children for the in-patient treatment of ophthalmia neonatorum, and the allocation of grants-in-aid to three hostels for boarding women and girls who are attending the clinics. The number of new patients suffering from venereal disease attending the clinics was 13,025 in 1917 and 23,514 in 1920, the principal increase having taken place in 1919. Early difficulties in staffing the clinics have passed away.

Essentials of an Efficient Clinic.

The report lays down the essentials of an efficient clinic. It must attract patients. There must be no undue waiting for treatment and reasonable privacy and sessions at convenient hours. It must be well-equipped and arranged so that there is no waste of the time of the medical staff. There must be provision at all hours of the day for intermediate treatment of gonorrhœa in both sexes by nurses and orderlies. The staff should be coördinated under one head and the medical staff should not be employed in doing work that can be done by clerks and orderlies. The hours at which sessions are held should be determined by the convenience of the patients, and the sessions should be sufficiently numerous to permit of each patient receiving the attention which is adequate to render him non-infectious in the shortest space of time. The conduct of the V.D. clinic, the report lays down, should be governed by the principle that it was established to render venereal patients permanently non-infectious, and that in every instance where it fails to accomplish this object it fails entirely to achieve the purpose for which it was established.

Facilities Available in 1920.

The facilities are not yet all that they should be. Most of the clinics are established in existing out-patient departments and the premises are used for other purposes between sessions. Intermediate treatment of gonorrhœa cannot be arranged satisfactorily. The restriction of hours causes congestion and overcrowding and delays detailed examinations. The rooms are not conveniently arranged; the lack of cubicles wastes the time of the medical officer and leads to undue exposure of the patients and want of privacy. It is obvious that more medical men are needed to staff inconveniently arranged clinics. To secure conveniently arranged clinics considerable capital expenditure is needed, and unfortunately no provision has been made for capital grants. A beginning has been made. During 1920 completely new premises especially designed for a venereal diseases clinic have been provided at St. Thomas's Hospital, and concurrently with the opening of these new premises there has been appointed a specially selected medical, nursing, and male orderly staff to permit of the facilities for diagnosis and treatment being available on week days from 8 A.M. until 10 P.M.

Selection of the Staff.

The selection of the staff is recognised as the most important factor in the success of the clinic. Special difficulties caused by the war have gone, but in some hospitals the work remains in the hands of members of the honorary staff without regard to the dominant consideration that ability and time to do the work properly should be foremost. Sometimes the medical staff is changed annually, rendering a high degree of efficiency impossible. Sometimes the head only attends occasionally and the real work is done by assistants. It is urged that the time has now come to appoint only men and women whose skill, knowledge, and experience in the diagnosis and treatment of venereal diseases is beyond all question, and to insist that those appointed should devote the time and attention necessary for efficient performance. Venereal diseases must no longer be a sub-department of dermatology, genito-urinary surgery, or gynæcology, and the medical officer in charge should have the same privileges and status as the honorary physicians and surgeons. The busy practitioner and the medical student have not been able to avail themselves much of the facilities for instruction offered at the clinics, and more should be done to encourage short-time paid clinical assistants. Payment of the staff is not at present on a satisfactory basis and the writers of the report see no difficulty in fixing a proper scale.

Improvement in Treatment.

The treatment of gonorrhœa, partly owing to the lack of intermediate treatment and partly owing to overcrowding or want of system, is reported to be specially unsatisfactory. More uniformity in the treatment of syphilis could be secured with advantage. The recording of toxic results from arsenobenzol treatment and the question of standards of cure need more attention.

Some of the reasons given for patients ceasing to attend before the completion of treatment are: (1) abatement of symptoms and optimism; (2) difficulty in accounting for repeated absences from work; (3) nature of occupation—e.g., seafaring, commercial travellers; (4) "not satisfied with treatment," "dislike of doctor or nurse," "hurt by injection," &c.; (5) careless or ignorant patients. The average of patients ceasing to attend before completion of treatment for the whole of the London clinics cannot be put at less than 30 per cent. and is probably higher. The remedies are (*a*) for the medical officer to impress the patient with the serious nature of his disease; (*b*) to study the convenience of the patients and abolish long periods of waiting, inadequate attention caused by congested clinics; and (*c*) the use of prominent notices in the waiting rooms, distribution of leaflets, and so forth.

In regard to stillbirths more effort might be made through the midwives to secure the examination of suspicious specimens and the attendance of infected mothers at the clinics for treatment.

Social Implications.

The report recommends that money should be spent in circulating information amongst voluntary societies concerned in hostel and rescue work, such as the Women Police, Police Court Missionaries, Y.M. and W.C.A., Church Army, Salvation Army. At the end of 1920 grants-in-aid were made to seven hostels with total accommodation of 86 beds for their assistance in securing the regular attendance at the clinics of women boarders. There are about 100 refuges and rescue homes in London with a total accommodation of some 2000 beds. These homes do not, as a rule, train their inmates to earn an independent livelihood but simply to help in the domestic work of the home.

Most of the rescue homes try to exclude girls suffering from venereal disease. The report records a universally expressed desire amongst rescue workers for the provision of what may be conveniently termed "reception houses," the function of which would be to provide immediate shelter for the night or until the girl could be sent to a suitable home. The rescue worker needs to take full advantage of the "psychological moment"; at present she often fails because she cannot find immediate accommodation for the girl. It is suggested that these rescue workers and homes are insufficiently acquainted with the activities of other bodies doing similar work and that a careful survey of the present position with a view to better organisation is needed.

Many of the rescued girls are suffering from venereal diseases, and towards the end of 1919 the M.A.B. provided a 52-bed hospital in Sheffield-street for women suffering from venereal disease who come into the hands of the women police patrols. The causes of prostitution are discussed. The report ends with extracts from "Downward Paths," Flexner's "Prostitution in Europe," and appendices give the experience of rescue workers and others.

THE LIVERPOOL PROPOSALS FOR CONTINUITY OF TREATMENT.

In his annual report for 1920 on the health of the City of Liverpool Dr. E. W. Hope writes: "To say that the position in regard to the prevention of mental state, the judge said he ought to be guided by the specialists, and he refused to make an order for her discharge. The intervals proper for her removal from control should be left to the mental specialists. He would make no order as to costs. He did not think the proceedings had been necessary. The case excited great local interest.

Women Hospital Residents.

The committee of the Melbourne Hospital recently considered the question of limiting the number of women appointed as hospital resident medical officers. The system of appointment at the hospital is that those highest in the honours list at the final examinations assume office according to their places. Thus it might happen that every place would be occupied by women in the first 12 or 15 places. At present there are five women residents out of 12 positions. The committee, after deliberation, declined to disturb the existing regulation.

Obituary.

The death of Mr. H. M. O'Hara, F.R.C.S.I., has recently occurred. Although born in Australia Mr. O'Hara was educated for the medical profession in Great Britain, and returned as a young man, at once attracting attention as a bold and brilliant surgeon. He was for many years surgeon to the Alfred Hospital, Melbourne, and his operating day was a kind of early post-graduate class. On reaching the age limit he was made consulting surgeon. Mr. O'Hara was a President of the Surgical Section at the Australasian Medical Congress about 20 years ago. He was, apart from professional work, a very well-known figure in Melbourne owing to his physical proportions and his many social interests, which ranged from horse racing to amateur opera. Mr. O'Hara was married three times and has a son in the medical profession.

The Services.

AUXILIARY ROYAL ARMY MEDICAL CORPS FUNDS.

THE usual quarterly committee meeting was held on Friday July 22nd, at 11, Chandos-street, when eleven grants were made to cases in the Benevolent Branch for the orphans of officers, amounting to £474 15*s.* 4*d.*, and five grants in the Relief Branch for widows and children of the rank and file, amounting to £109.

These Funds are for the relief of widows and orphans of commissioned officers, non-commissioned officers, and men of the rank and file of the Royal Army Medical Corps, Special Reserve, Territorial Force, and new armies, and also for the relief of those who have been so severely damaged in the late war that they need help for the education of children. Requests for relief should be addressed to the Hon. Secretary, at the offices of the Funds at 11, Chandos-street, London, W. 1.

THE sword for colonels, Army Medical Service, and officers of the Royal Army Medical Corps, will in future be of the pattern authorised for infantry. Officers in possession of the existing pattern sword may retain it in wear. The gorget patches worn by the Army Medical Service are now of dull cherry cloth.

THE HEALTH AND COMFORT OF THE SOLDIER IN INDIA.

The Territorial Army can claim to have done much to ameliorate the conditions of service of the soldier in India. Prior to their "occupation" during the war electric light and fans were unknown luxuries in Indian barracks, hospitals, and bungalows, but as the result of insistent efforts, light and fans are now installed in all the principal cantonments. A large installation to serve the whole district has just started working in Peshawar and a similar installation should be working at Umballa before the end of the year. These things, and the wider employment of nurses, are very important medical reforms, affecting the health and comfort of the soldiers.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Commr. A. C. W. Newport, M.V.O., Surg. Lieut.-Commr. A. Lawrey, L.D.S., and Surg. Lieut. H. E. Y. White to the *Renown.*

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. H. Hewetson retires on ret. pay and is granted the rank of Col.

Maj. C. R. L. Ronayne retires on ret. pay and is granted the rank of Lt.-Col.

Capt. D. G. Evans from Spec. Res. to be Capt.

Capt. J. L. Ritchie retires, receiving a gratuity.

G. L. K. Finlay, late temp. Capt., to be temp. Capt.

M. H. Carleton to be temp. Lt.

Officers relinquishing their commns.: Temp. Capts. J. T. Hill and F. J. R. Cowie.

Temp. Capts. granted the rank of Maj.: A. G. Welsford and C. Sullivan.

Temp. Capts. retaining the rank of Capt.: R. Hodson, D. E. Hearn, and H. L. C. Noel.

Temp. Hon. Capt. A. C. Delacroix retains the hon. rank of Capt.

SPECIAL RESERVE OF OFFICERS.

Capt. A. J. Gibson relinquishes his commn. and is granted the rank of Maj.

Capt. E. D. D. Dickson relinquishes his commn. and retains the rank of Capt.

TERRITORIAL FORCE.

Lt.-Col. A. G. Hay from 3rd Sco. Genl. Hos. to be Lt.-Col.

Lt.-Col. A. R. Wilson resigns his commn. and retains the rank of Lt.-Col., with permission to wear the prescribed uniform.

Maj. C. H. Lindsay, D.A.D.M.S., 55th (W. Lan.) Divn., to be Bt. Lt.-Col.

Capt. E. Alderson to be Maj.

Capt. T. S. Elliot resigns his commn. and is granted the rank of Maj.

Hon. Surg. Capt. C. T. Fox (late East Kent Yeo.) to be Capt.

Lt. C. S. Atkin (late R.A.M.C.) to be Lt.

The undermentioned Majs., having attained the age limit, are retired and retain the rank of Maj., with permission to wear the prescribed uniform: J. Robinson, C. S. de Segundo, J. F. F. Parr, and F. J. Oxley.

The undermentioned, having attained the age limit, are retired and retain their rank: Maj. J. E. B. Wells, and Capts. E. V. Phillips, F. Jeffree, A. Scott-Turner, C. Telfer, J. F. Farrow, and A. G. Wilson.

2nd Western Gen. Hosp.—Lt.-Col. Sir Wm. Thorburn, having attained the age limit, is retired, and is granted the rank of Col., with permission to wear the prescribed uniform.

Lt.-Col. E. S. Reynolds, having attained the age limit, is retired, and retains the rank of Lt.-Col.

Maj. A. Wilson, having attained the age limit, is retired, and is granted the rank of Lt.-Col.

Maj. R. B. Wild, having attained the age limit, is retired, and retains the rank of Maj.

Maj. A. H. Burgess resigns his commn. and retains the rank of Maj.

TERRITORIAL FORCE RESERVE.

Capt. W. J. Gray, from Gen. List, to be Maj.

Capt. D. Smith, from 2nd Lond. Sanitary Co., to be Capt.

INDIA AND THE INDIAN MEDICAL SERVICE.

Lt.-Col. to be Col.: W. Young.

Maj. C. Thomson, retd. list, to be Lt.-Col. retd. list.

Lt.-Col. A. M. Fleming to be actg. Col. while holding an appt. as A.D.M.S.

Maj. A. G. Tresidder to be actg. Lt.-Col. while comdg. an Ind. Gen. Hosp.

The King has approved the retirement of Bt. Col. W. W. White.

Major A. C. Ingram, professor of medicine, General Hospital, Madras, has proceeded on a year's leave; Major G. E. Malcolmson officiates for him. Lieut.-Col. James Masson, civil surgeon, has been appointed Superintendent of the Bhagalpur Central Jail. Lieut.-Col. R. A. Lloyd, civil surgeon, has been appointed to the executive and medical charge of Hoshangabad District Jail. Lieut.-Col. W. M. Anderson resumes his appointment as Chief Medical Officer, North-West Frontier Province. Lieut.-Col. S. E. Prall and C. M. Goodbody retire from the Service. Lieut.-Col. E. Ryan has been appointed Honorary Surgeon to the Viceroy. Lieut.-Col. J. G. G. Swan, C.I.E., has vacated the appointment of superintendent District Jail, Ferozepore. Capt. S. R. Rao, deputy sanitary commissioner, officiates as Sanitary Commissioner of Assam, vice Mayor Taylor, granted a year's leave.

and other blemishes from the faces of his customers. It was stated in his defence that he had gained experience in America and Paris, and that he "had held" a licence for face treatment from the L.C.C. A qualification mentioned was an honorary degree from the Oriental University, Washington. In fining him the magistrate observed that it was not for him to judge as to the success of the defendant's methods, which seemed to him to be highly dangerous.

Control and Drunkenness.

A question was asked recently in the House of Commons by Colonel Sir Arthur Holbrook, M.P., as to whether statistics were available showing the comparison in the number of convictions for drunkenness in controlled and uncontrolled areas; and whether the percentage of such convictions was lower, for example, in uncontrolled Herefordshire, than in controlled Worcestershire, and in uncontrolled West Suffolk than in controlled East Suffolk. The Home Secretary's answer was to the effect that all available statistics would be found in the annual volumes of Licensing Statistics, of which the volume for 1920 is now obtainable. Accurate comparison would, however, be difficult for many reasons, including the fact that the scheduled areas do not necessarily correspond with the areas for which figures are shown. This seems equivalent to a negative reply, but after all, whatever might be shown by the figures asked for, they would be unlikely to convert the more stalwart advocates of decontrol or of continued control respectively to the views of their opponents. After all, either side may be right, but figures alone, without full particulars of social and industrial conditions, prove very little in such a case. At present it is open to the advocates of continued control to say that it has been used in certain districts because they require it, and that Herefordshire and West Suffolk are to be congratulated not because they have not been controlled but because they have not needed it. On the other hand, the figures for Worcestershire and for East Suffolk, after a year or two without control, may some day supply an answer to one side or the other such as it has never had at its command before, and may prove either that control is an effective weapon for promoting temperance, or that it is of negligible importance to that end. The case for or against control may also be better established than by statistics of convictions.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

School Instruction in Venereal Disease.

THE Council of the Department of the Seine is considering a suggestion referred to it by the Société de Médecine Publique et de Génie Sanitaire in regard to introducing into the school syllabus some instruction in venereal diseases and their consequences. It appears necessary to the Société to warn youths and girls against the dangers of venereal diseases before leaving school, when they should be told that abstention from non-conjugal sexual connexion is the best of prophylaxis as well as a moral duty. The Société also emphasised the necessity of pointing out to adults and more especially to soldiers the safety that derives from the use of specific ointments, recommending only those of which the formula has been officially tested and proved.

Prophylaxis Against Influenza.

Mr. R. Dujarric de la Rivière made a communication on the prophylaxis of influenza at a recent meeting of the Société de Médecine Publique et de Génie Sanitaire. He accepted the initial cause of influenza to be a filtrable virus, the complications being due to bacterial secondary infections. Prophylaxis should concentrate on general measures directed against the transmission of the virus and on special measures of protection against the complications. The public should realise the necessity of temperance in alcoholic consumption for every individual living in an epidemic area. The danger should be indicated of excessive use of antiseptic gargles and nasal washes in causing inflammation, mucous irritation, and so diminishing resistance to infection, as well as the value of frequent washing of face and hands and of disinfecting dwellings. Cats and dogs had been shown to transmit the virus, and in an epizoötic of horses hæmoculture had revealed an organism similar to Pfeiffer's bacillus, associated with pneumococcus and streptococcus. The blood serum of convalescent horses had shown definite therapeutic action when injected into patients suffering from influenza. The author insisted on the need of isolating suspects as well as well-recognised cases during any local out-break and treating them in fever hospitals or in special blocks of general hospitals. Doctors and nurses should wear overalls and masks when on duty. Nurses should wash their hands with surgical care when going off duty, and doctors should do the same on leaving the wards. Mr. Dujarric de la Rivière went on to give instances showing that convalescing patients are not likely to contaminate other people. He recommended polyvalent vaccine against complications. Immigrants should be refused admission from any country suffering from an epidemic of influenza, and he regretted that no international conventions had yet insisted on quarantine regulations. In the event of an epidemic a regular mobilisation system should be arranged, this mobilisation comprising extempore hospitals of hutments and tents, the requisition of cars to transport patients, and prohibition of public gatherings. In non-epidemic times the public should be instructed in schools, through the distribution of pamphlets and by special cinema films at frequent intervals.

Periodic Medical Examination of School Children.

The Conseil Municipal de Paris has decided to ask its school medical officers to undertake a general medical examination of Paris school children every two months, and to record the condition of the mouth and teeth on a special sanitary card. When necessary, the children will be sent to dental surgeries selected for the purpose by the authorities.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Relation of Alcoholism to Crime.

AT a meeting of the Society of Medical Practitioners, Dr. Geró, medical expert attached to the law courts, reported that of 94 individuals charged with homicide or attempted homicide, examined by himself, there were six malingerers and four persons who were wrongly supposed to be the subject of mental defects. Of the remaining 84 criminals only 14 were females. The following conditions of health were noted: one case of pregnancy, with mental derangement, one of morphiomania, one of hysteria, nine cases of delusions of persecution, seven of various states of mental disorder, eight of hysteria or epilepsy, 13 of various diseases either supposed or known to have an effect on the brain, 10 of mental defect, and 34 of alcoholism. Dr. Gero emphasised the fact that alcoholics formed more than a third of the total number of persons charged with homicide. He added that an examination of the antecedents of criminals grouped under other headings would show that many of the epileptics and mental defective subjects were the children of alcoholic parents. He also pointed out that acts of extreme violence might be committed not only by habitual inebriates but also by persons in a state of occasional alcoholic intoxication, in illustration of which he quoted cases.

WAR EMERGENCY FUND OF THE R.M.B.F.: GRANTS FOR EDUCATION.

To the Editor of THE LANCET.

SIR,—The War Emergency Fund of the Royal Medical Benevolent Fund was founded in 1916 to assist medical men after their service abroad when they returned to practice. The Committee have already expended £18,000 in grants; they still have ample funds in hand and are prepared to make liberal grants towards the cost of education, and, if necessary, to pay the school fees of the sons or daughters of any medical man who, as the direct consequence of having held a commission in the Army Medical Service during the late war, finds himself unable to give as good an education to his children as he would otherwise have been able to do. The Committee are also prepared to consider applications for grants in such cases in order to aid in education at the Universities and the Medical Schools, and in training for professions.

I am, Sir, yours faithfully,

G. NEWTON PITT,
Hon. Sec.

11, Chandos-street, W. 1, August 14th, 1921.

ÆTIOLOGY OF ASYLUM DYSENTERY.

To the Editor of THE LANCET.

SIR,—The valuable contribution to the ætiology of bacillary dysentery in asylums by Dr. W. S. Dawson and Dr. W. Moodie, published in THE LANCET of July 30th, must appeal to all interested in asylum administration, for the emphasis which it lays on the importance of routine bacteriological examination of the stools from all cases of diarrhœa. There is, however, another aspect of the problem of asylum dysentery which, I think, merits careful consideration before adopting the somewhat drastic measure of complete and permanent isolation of all cases. In any case of infection there exist two varying factors—the degree of susceptibility of the individual to infection, and the degree of virulence of the pathogenic organism. If we postulate that, in the insane, opposition to bacterial infection is lessened, it becomes clearly a matter of importance to investigate the possible source or sources of this failure of resistance, with a view to adopting the appropriate remedy.

Recent experimental research into the influence on nutrition of certain accessory food factors gives a new importance to the subject of asylum dietaries, and raises the question whether certain diseases prevalent in mental institutions may not own their perpetuation to an inadequate supply of vitamins. It needs but a small acquaintance with asylum life to learn that it is a particular class of case, the chronic demented inmate, who is liable to attacks of dysentery; and it is also a familiar fact that members of the nursing staff are almost never attacked, in spite of their constant attendance on such cases and their sometimes imperfect acquaintance with the principles of disinfection. The former class are compelled by their circumstances to accept a diet which, though adequate in amount, cannot satisfy the individual craving for certain articles of diet, a craving which possibly may be interpreted as an instinctive attempt to obtain certain essential food factors. Apart from such a theoretical consideration, it is a matter of common knowledge that the supply of a well-balanced diet for the insane becomes increasingly difficult during the winter months, when fresh vegetables are difficult to obtain, and it is a significant fact, as Dr. Dawson and Dr. Moodie point out, that the highest incidence of dysentery occurs during the period of January to April.

By feeding pigeons on a diet deficient in proteins, fats, and certain accessory food factors, McCarrison has shown that changes are produced which favour infection of the mucous membrane of the bowel by pathogenic organisms. It is possible, as he suggests, that these experimental results are applicable in some degree to man, and that a long continued subminimal supply of accessory food factors may lead to conditions favouring the development of gastrointestinal disorders. During the late war I had at one period charge of a large number of prisoners of war, many of whom suffered from both dysentery and scurvy; in such cases the generous diet of a British hospital by itself produced effects so striking that I became convinced that dysentery may, in part, be a "deficiency" disease. The final proof of such a conception will be forthcoming when it is shown possible to diminish the spread and relapse of asylum dysentery by a more careful attention to the *qualitative* deficiencies of asylum diet, and it is on these lines that work is now proceeding in this institution.

It may be true that dysentery is to a certain extent spread by individuals in good health who harbour the bacilli, but in my experience the most important source of outbreaks is the presence of mild relapsing cases, who are not in the true sense of the word carriers, and it is surely a policy of despair to recommend their permanent isolation in preference to measures directed to their cure.

I am, Sir, yours faithfully,

Whittingham Asylum, August 8th. R. M. STEWART.

THE WEANLING IN UPPER EGYPT.

To the Editor of THE LANCET.

SIR,—I was interested in the letter from Dr. W. E. Nickolls Dunn which appeared in THE LANCET of May 28th, as his remarks upon the weanling in Upper Egypt apply to the natives of the Northern Provinces of Nigeria, where also gastric ulcer, appendicitis, and carcinoma are almost unknown diseases. There is, however, a marked difference between the condition of the teeth of our natives and of those of the country Arabs of Upper Egypt, as will be seen from the following figures upon incidence of pyorrhœa, prepared by Dr. J. W. Thomson and myself in 1913 by examination of 400 prisoners in two large gaols:—

Number with pyorrhœa	..	317 or 79·2	per cent.
" with carious teeth	..	82 " 20·5	"
" with teeth missing	..	87 " 21·7	"

This incidence of pyorrhœa and dental caries among our natives is probably due to the fact that their diet, after weaning, consists almost entirely of cooked food—guinea-corn ground and made into stiff porridge, with oil (ground-nut or palm-oil) boiled with vegetable and peppers and sometimes meat or fish; yam or cassava may replace the guinea-corn; half-cooked or "toasted" meat is taken, as is shown by the frequency of tænia infections. Practically no fresh fruit is available, but sugar-cane is chewed when in season. Upon this diet the bowels act naturally two to three times a day, and relief is immediately sought in the event of constipation. In other words, the native, like a herbivorous animal, lives upon a bulky diet and opens the bowels frequently. I would, therefore, tentatively suggest that absence of intestinal stasis rather than absence of dental caries may be the reason for the comparative scarcity of gastric ulcer, appendicitis, and carcinoma.

My native work, largely surgical, involves treatment of roughly 90 per cent. natives of Northern Nigeria and 10 per cent. coast natives. The latter correspond to the Cairo natives mentioned by Dr. Nickolls Dunn, in that they live largely upon European food, including bread made from flour ground in England. Case incidence of gastric ulcer, appendicitis, and carcinoma may be judged from the following figures of the last 750 surgical operations I have performed in Nigeria.

No cases of gastric ulcer. Never seen post mortem during nine years' work.

Four cases of appendicitis or appendix abscess. Two of these were in coast natives and should be excluded. One doubtful case of retro-cæcal suppuration, one true appendix abscess in N. Nigerian.

members of the Municipal Council who, more often than not, have their own axes to grind when any question affecting the health of the town is brought up by the health officer.

The local and municipal conference at its meeting in July, 1920, discussed the whole question at considerable length, and in spite of a strong feeling that local bodies should have full powers of appointment, &c., in regard to their officers, a resolution was passed to the effect that the posts of health officer be provincialised, subject to the same conditions in regard to control, postings, and transfers as those of medical officers—viz., that the powers of control over their servants vested in local bodies should not be prejudicially affected, and that the Surgeon-General should ordinarily consult local bodies in the matter of posting and transfers. This meant that health officers should be lent to local bodies in the same way that civil assistant surgeons and sub-assistant surgeons are lent at present.

Government Adoption of the Proposal.

The Financial Relations Committee and the Public Health Board of Madras both endorsed the recommendation, and in view of the consensus of opinion the Government have recently decided to accept the proposal; orders have now been issued to the effect that the Government consider that there should be two grades of health officers, whose appointments should be included in one or other of the two existing provincial cadres of civil assistant surgeons and sub-assistant surgeons. First-class health officers should possess the L.M.S. degree of the University of Madras or some other equivalent or higher medical qualification; second-class health officers should possess the L.M.P. diploma or an equivalent qualification, and both classes should have undergone a year's special training. Special arrangements will be made for instituting a suitable course of training, with effect from July 1st, 1921, to which all assistant and sub-assistant surgeons will be eligible. Health officers will draw pay on the scale fixed for the service to which they belong, an additional local allowance being made as compensation for loss of private practice.

Further orders state that the rate of local allowance will be calculated with reference to the total service of the officers as civil assistant surgeons or sub-assistant surgeons, not as health officers. Health officers employed in municipalities will also be granted fixed conveyance allowances, and those employed under local boards will draw travelling allowances under the ordinary rules in the Civil Service regulations. The number of appointments to be sanctioned depends mainly on the requirements of local bodies; the Government consider that health officers of the first class should ordinarily be employed under all district boards, in municipalities with a population of 50,000 or more, and in important sanatoriums, whilst in other municipalities second-class health officers may be employed. The question of the proportion of the salaries of health officers to be paid from provincial and from local funds, with the bearing on that question of leave and pensionary contributions by local bodies in respect of officers lent to them, is under separate consideration. With a view further to improve the prospect of health officers the Government propose that in future recruitment to the grade of Deputy Sanitary Commissioner should ordinarily be made from the ranks of health officers possessing the requisite qualification. The Government will be informed as early as possible which of the local bodies are willing to employ health officers, and whether first- or second-class health officers are required.

Training of Health Officers.

It has now been decided that health officers should be provided for 25 district boards and 78 for municipalities, 13 of these being first class and 65 second class. The Government have approved the Surgeon-General's proposal that the syllabus laid down for the Madras University B.S.Sc. degree should be adopted for the training of all health officers; and the separate course of training formerly prescribed for second-class health officers should be abolished. They have also decided that every facility should be given for research work and the investigation of disease, and that for this purpose they should be provided with a small laboratory and a microscope. The first class held under these new rules commenced on July 4th and 20 suitable candidates were selected for the course from a large number of applicants. The medical college is unfortunately unable to accommodate a greater number, and it will therefore be a few years before a sufficient number of trained men are available. It is of some satisfaction, however, to know that this problem is at last on the way to solution.

Madras, July 20th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Folie Circulaire.

A CASE presenting some unusual features has just occupied Mr. Justice Street in Sydney, sitting as Judge in Lunacy. The wife of a man of academic distinction, resident in New Zealand, had in 1912 exhibited such mental peculiarity as to require special detention. She was allowed out with a nurse the following year, but relapsed and was again detained in 1911 and 1915. As there was no suitable private mental institution in New Zealand, her husband arranged for her transfer to New South Wales, and she entered Mount Saint Margaret's Hospital in 1915 under fresh certificates. She was allowed out in 1916, but was again admitted in 1917, and once more in 1919. In 1921 she was transferred to the State Mental Hospital at Gladesville. The present proceedings took the form of a special judicial inquiry at the instance of Mr. G. S. Thompson, F.R.C.S., who alleged the lady was perfectly sane. Mr. Thompson had been consulted professionally in October, 1920, by the patient, who was then on probation and living privately. Mr. Thompson did *not* know anything of her mental condition. He advised her to go into hospital for the purpose of an operation. The lady in whose care the patient was then living told him she was on probation and under the care of Dr. A. Davidson. Mr. Thompson stated that he had then telephoned Dr. Davidson, but that gentleman declined to recognise him in the case and refused to inform him of the patient's subsequent whereabouts. Mr. Thompson then began an agitation for a public inquiry, which resulted in the present proceedings. In cross-examination Mr. Thompson denied that he was allied to the Socialist party, but admitted he wore a red flower and lectured at Labour party meetings. Portions of a letter from Mr. Thompson to the Premier of New South Wales were read, in which were the following words:—"From the evidence before me it appears that something very improper is going on in this matter. The case requires sifting to the bottom. Mrs. —— is certainly not insane now, whatever her condition was. It is scandalous that certain persons who are gaining thereby should have power to kidnap people and keep them in prison at their own sweet will." Dr. Richard Arthur, M.L.A., Mr. Donald Fraser, M.B., and Dr. J. B. Nash, M.L.C., gave evidence that they had not found indication of the patient's insanity. Mr. W. G. C. Smith, M.B., Dr. Andrew Davidson, Dr. Eric Sinclair, Inspector-General of the Insane in New South Wales, Dr. Chisholm Ross, Dr. W. C. Williamson, and Mr. H. C. McDouall, Medical Superintendent at Gladesville, all having special alienist experience and training, testified that she was suffering from periodical insanity. Mr. Justice Street in giving judgment said that there were elements in the case which might excite suspicious people, but animadverted strongly on the language used by Mr. Thompson and his imputation of dishonesty against those in charge of the patient. He thought the latter's husband had been animated throughout by a desire to do the best. As to her sideration of their treating sick and wounded soldiers and sailors.—Lieut.-Col. Hon. G. F. STANLEY (Financial Secretary to the War Office) replied: The amount paid during the period in question to the London voluntary hospitals for the maintenance and treatment of soldier patients was about £880,000. I regret that I cannot give the sum paid in respect of each year, but I hope this will be sufficient for my hon. friend's purpose.

The Size of a Panel.

Mr. PURCHASE asked the Minister of Health the maximum of patients a doctor might have upon his panel; and to what extent he might increase this number by having assistant doctors.—Sir A. MOND replied: The limit of the number of insured persons whom an insurance practitioner may have on his list is determined by a scheme made for each area by the Insurance Committee and the Panel Committee jointly, and the extent to which the limit may be increased where the doctor engages one or more permanent assistants is determined by the Insurance Committee, who is required to have regard to the particular circumstances of the doctor's practice. No doctor working single-handed may have more than 3000 persons on his list, the maximum has been fixed in a large number of areas at 2000 to 2500, and the average number per doctor is approximately 1000.

Nurses' Registration Rules.

Lieut.-Colonel Sir JOHN HOPE asked the Minister of Health whether, under the rules for registration of nurses now lying upon the table of the House, a nurse who had been trained in Scotland and was practising in Scotland could be admitted to the English Register, and thereby remove herself entirely from the jurisdiction of the Council of the country in which she was practising; and whether he would consider the amendment of both the English and Scottish rules so that all nurses should originally register in the country in which they were practising, but should be able to be placed on the Register of the other country without difficulty or payment if they subsequently desired to practise in that other counrty.—Sir A. MOND replied: I am advised that it is not competent to the General Nursing Council to refuse to admit to the Register a nurse who is otherwise qualified on the ground that she is not practising in the country. Registration is purely voluntary, and no nurse can be brought within the jurisdiction of any of the three Nursing Councils except by her own choice. A nurse practising in Scotland would derive no advantage from admission to the English Register, since she would not thereby be entitled to describe herself in Scotland as a registered nurse.

Small-pox in Madras.

Mr. WATERSON asked the Secretary for India whether his attention had been drawn to the exceptionally heavy epidemic of small-pox which occurred in the Madras Presidency during the years 1917, 1918, and 1919, when the deaths were 31,058, 58,752, and 41,732, respectively, the number in 1918 representing nearly two-thirds of the total number of deaths from small-pox in British India; and whether any special investigation had been made of the causes of the epidemic and of the failure of vaccination to prevent it, particularly in view of the fact that vaccination was compulsory in all the municipalities, and in 193 villages and 70 ranges of the Presidency.—Mr. MONTAGU replied: I have seen reports containing these figures. The heavy mortality is attributed to laxity in enforcing vaccination and especially re-vaccination, and to inadequate scrutiny of the results. A reorganisation of the vaccination staffs in Madras was sanctioned in 1918, and is probably now in working order. I would add that sanitation is a transferred subject under the new Indian Constitution—i.e., that it is no longer under my control.

THURSDAY, AUGUST 11TH.

Pensioners' Deaths.

Mr. TYSON WILSON asked the Minister of Pensions the number of persons who, having been granted pensions owing to injuries or disease caused by the late war, had died since the pension was granted them.—Mr. MACPHERSON replied: The approximate numbers are, I regret to say, officers 1150, and other ranks 45,000.

Lady Superintendents at Holloway Prison.

Viscountess ASTOR asked the Secretary for the Home Department whether the lady superintendents recently appointed in Holloway prison possessed medical or nursing qualifications: if not, what other qualifications they possessed; and what were their duties and powers.—Mr. SHORTT replied: One of these ladies is a highly qualified nurse, who has had much experience in charge of outside hospitals. She has the supervision of all the hospital work of the prison and of the hospital staff, subject to the control of the medical officers, and the Governor, who is a medical man. The other has had great experience as a prison officer, and has the supervision of the disciplinary side of the prison with its staff, subject to the control of the Governor.

Dangerous Drugs Regulations.

Mr. GILBERT asked the Secretary for the Home Department whether the regulations under the Dangerous Drugs Act, 1920, had been officially confirmed and were now in operation; and what other powers had passed legislation in accord with the Opium Convention of 1912, so as to secure coöperation in regard to the import and export of the dangerous drugs named in the Act.—Mr. SHORTT replied: The Regulations have been made and will come into force on Sept. 1st. I cannot say definitely what other powers have passed legislation to carry out the Convention of 1912, but the powers which were signatory to the Treaties of Peace undertook to enact the necessary legislation without delay and at latest within 12 months from the Treaties coming into force. I understand that full information as to the position in each country is being collected by the League of Nations, which is entrusted with the general supervision over the execution of the Opium Convention.

MONDAY, AUGUST 15TH.

New Taxation of Motor Vehicles.

Sir HARRY BRITTAIN asked the Minister of Transport whether, seeing that six months had passed since the new form of taxation for motor vehicles was introduced, he was now able to give the House some information as to the methods in which the large sum of money obtained was being used in the development and improvement of the roads and for other purposes.—Mr. A. NEAL (Parliamentary Secretary to the Ministry of Transport) replied: The greater part of the net yield of the new taxation is being applied in grants under the classification scheme whereby local authorities receive contributions towards their approval expenditure on roads ranking as first and second class. Local authorities were advised that a balance would be available for the purpose of various improvements, and they were invited to submit such schemes by the end of July last. These schemes are now under examination.

Disabled Naval Men in Hospital.

Mr. ANEURIN WILLIAMS asked the Parliamentary Secretary of the Admiralty how many naval men were still in hospital suffering from disabilities due to the war.—Mr. AMERY replied: The number of serving naval men who are suffering from disabilities due to the war and still under treatment in hospital is 18. In addition, there are five naval men in naval hospitals who have been discharged from the Navy and are in receipt of pensions from the Ministry of Pensions. There are also 113 naval men under treatment in Royal Naval Hospital, Great Yarmouth, suffering from disabilities due to the war. This does not include naval men still being treated under Ministry of Pensions in hospitals other than naval.

TUESDAY, AUGUST 16TH.

Ex-Service Men in Hospital.

Mr. ANEURIN WILLIAMS asked the Minister of Pensions how many ex-Service men were still in hospital suffering from disabilities arising from or aggravated by service in the war.—Major TRYON replied: The number of ex-Service men at present receiving in-patient treatment from this Ministry for disabilities due to or aggravated by service in the Great War is approximately 34,000. This figure includes 2600 men undergoing concurrent treatment and training.

Business Committee and Medical Services.

Lieut.-Colonel FREMANTLE asked the Chancellor of the Exchequer if the advisory business-men's committee would consider the waste incurred in the maintenance under 12 Government departments of separate public medical and nursing services with separate institutions and personnel, separate means of recruitment, separate purchase of stores and equipment, often overlapping, often in peace-time redundant, to meet needs which to a large extent were the same, and on active service were often discharged by mutual assistance; and whether in any such consideration they would be assisted by persons having direct experience of such services.—Mr. HILTON YOUNG (Financial Secretary to the Treasury) replied: Pending detailed examination of the departmental replies to the Treasury circular of May 13th last, it would be premature for me to express an opinion with regard to the alleged duplication of machinery, but the matter will be carefully investigated.

THE Great Northern Central Hospital, Holloway, has received from King Edward's Hospital Fund a grant of £1550 for the new Nurses' Home and other extensions from the final distribution of surplus Red Cross funds.

Public Health Services.

Hospital Collections in London.

A CIRCULAR has been issued to the London hospitals by King Edward's Hospital Fund dealing with the subjects of collections from employees and the coördination of appeals for support. The Fund has lately coöperated with the London Regional Committee of the British Hospitals Association, the Hospital Sunday Fund, the Hospital Saturday Fund, and the League of Mercy in discussion of these points and the various factors bearing upon them. The King's Fund Policy Committee and the Conference of Central Agencies have decided not to pass binding resolutions until the discussion has been completed, and evidence on a good many aspects of the subject is still inadequate. The circular contains outlines of the discussions at present proceeding. It is suggested that for purposes of collection from employees the metropolis (within nine miles of Charing Cross) be divided into hospital areas around key hospitals, and that the willingness of these hospitals to coöperate with the conferring agencies be ascertained; that when an area with a key hospital is adopted, a committee be formed consisting of local representatives of the organisations concerned to facilitate the securing of maximum collections; and that a general arrangement might be made whereby the coöperating hospitals should be assured of a due proportion of the proceeds of collections.

No proposals have yet been formulated for a change in the existing practice as regards weekly contributions. A list of London hospitals, geographically arranged, with the adjacent municipal areas, Hospital Saturday Fund areas, and League of Mercy areas, is enclosed with the circular to facilitate consideration of the existing facts. Some hospitals already contemplate the holding of local conferences, and the King's Fund Policy Committee holds itself ready to receive observations from hospitals, and to assist in the summoning of such conferences. With regard to coördination of appeals, no general statement has yet been prepared; in the meantime the individual hospitals remain at liberty to act on their own judgment in the matter of appeals, other than for capital expenditure, without reference to the King's Fund.

Private and Panel Practitioners.

Our correspondent, "Non-Panel," in THE LANCET of August 13th disputes our contention that the practice of charging fees to insured persons by non-panel practitioners is seriously prejudicial to the medical service of the insured. He makes a number of good points, but he misses the essential one. It may well be that such an arrangement satisfies all parties, but it leaves the insured person with the impression that by going to the non-panel practitioner and paying fees he is getting a superior form of treatment. This impression certainly creates a prejudice against the treatment provided by the Insurance Act. By not putting his name on the medical list the non-panel practitioner limits the choice of insured persons, and those of his patients who are insured persons have to pay a second time for what is guaranteed to them by the Act. Should the doctor of his choice not be on the panel any insured person may apply to make his own arrangements, and may receive his medical benefit from the non-panel doctor under certain conditions. The doctor who accepts these conditions naturally has to guarantee that his attendance on the insured will not be inferior to that provided under the Act by insurance practitioners.

ANNUAL REPORTS OF M.O.H.

Reading.

THIS report for 1920 describes very fully the complete health organisation which Dr. A. Ashby, after 33 years' service, has left to his successor, Dr. H. J. Milligan, to carry on. Dr. Milligan, in his introductory letter, says: "Appointed in the year 1887, Dr. Ashby was medical officer of health for a period of 33 years, a period which, the perusal of this report will show, witnessed enormous strides in the public health of the district. In June, 1920, he was appointed consulting medical officer while still retaining the office of public analyst."

The year under review shows an improvement even on the highly satisfactory returns of previous years. In respect of death-rate from all causes, infant mortality rate, and tuberculosis death-rate, Reading compares very favourably with other large centres of population.

The housing shortage continues and considerable numbers of the population are still compelled to live under very undesirable conditions. Certain courts containing 70 houses which are very old and in some cases bordering on collapse have to remain occupied, and two unhealthy areas comprising 59 and 211 houses respectively, cannot be dealt with until the acute housing shortage is relieved. The council have adopted a scheme for the provision of 600 houses. Work has been begun on 162 and at the end of the year 50 were completed and occupied. There were also 28 houses built by private enterprise, for 21 of which a subsidy was granted. "The general standard of housing in the district is good. Where the actual structure of the houses often leaves much to be desired the situation is frequently relieved by the general lay-out scheme, most of the streets being wide and the majority of the houses having gardens." The occupations—biscuit manufacturing, engineering, railway work, seed growing, printing, lithographing, &c.—"have no special determining influence on the health of the inhabitants." The Registrar-General's estimate of the population is, for birth-rate 95,387 and for death-rate 95,006. The birth-rate, 23·8, is the highest recorded since 1905 and has risen from 16·7 in 1919. The death-rate 10·7, the infant mortality rate 66·7, and the tuberculosis death-rate 0·96 have to be compared with rates for the preceding decennium of 12·66, 83·3, and 1·32 respectively.

The water-supply derived from the river Kennet is passed through mechanical filters and is, in addition, chlorinated by the use of a solution of bleaching powder. The sewage is at present treated by broad irrigation on the corporation manor farm, but it has been decided to adopt the "activated sludge" system. The extension of the sewerage system to Tilehurst will enable the 563 pail-closets to be converted into water-closets. "The work of emptying pail-closets and cesspools is done by the householders and is carried out without nuisance."

Examination of milk samples for tubercle bacilli was given up during the war and is to be resumed. Inability to obtain convictions for milk samples deficient in milk fat varying from 17·7 to 13·3 per cent., shows the need for alteration in the law. Only about 17 per cent. of the infants born in 1919 were vaccinated. There is difficulty in getting early notification of tuberculosis; arrangements have been made for the treatment of pulmonary and non-pulmonary tuberculosis at the Headington sanatorium extension of the Radcliffe Infirmary, Oxford. A pavilion at the isolation hospital is in use chiefly for advanced cases. The school dentist attends to the teeth of tuberculous patients. During the year 491 new cases of venereal disease were treated at the V.D. clinic established at the Royal Berkshire Hospital for Berkshire, Wiltshire, and Reading. There are four centres for infant consultations, an antenatal clinic opened in October is being well attended, and a maternity home was opened in September. Owing to the extreme trade depression £1250 (net) was spent under the Milk Order, 1919, during the year ending March 31st, 1921.

For a "garden city" like Reading the death-rate of 6·5 per 1000 births for diarrhœa and enteritis under 2 years seems rather high, and the damage rate for 15 cases of notified ophthalmia neonatorum is also high—viz., the sight of one eye permanently affected in two cases and the sight of one eye completely lost in another.

Sir StClair Thomson has had conferred on him the Order of Chevalier de la Légion d'Honneur for services rendered in France with the Croix Rouge Française during the war.

CARE OF FEMALE MENTAL DEFECTIVES AT HULL.—On August 5th Tilworth Grange, in the parish of Sutton-in-Holderness, was formally opened by the Lady Mayoress of Hull as an institution for the care of female mental defectives. The property was acquired at a cost of £9000, and consists of a large house with numerous out-buildings, and an estate of 21 acres. Half the sum named (which includes expenditure on alterations and equipment) will be met by the Board of Control. There is accommodation for 50 patients of all grades; the staff includes a female gardener who will instruct the patients in gardening.

Appointments.

DUNDAS-GRANT, Sir JAMES, M.D., has been appointed Consulting Laryngologist to the Cancer Hospital, Fulham.

PERKINS, R. J., M.B., B.S. Lond., Physician to Out-patients' Department of the Royal Waterloo Hospital.

ROBERTS, C. S. LANE, M.S. Lond., F.R.C.S. Eng., University Tutor in Obstetrics and Resident Medical Officer, Maternity Hospital, Leeds.

TOPALIA, H. A., L.R.C.P. & S. Edin., L.R.F.P. & S. Glasg., Assistant Medical Officer to the Swaffield-road Institution and Intermediate Schools, Wandsworth Union.

Vacancies.

Queen Mary's Hospital for the East End, Stratford, E.—Cas. O. £150.
Rochester, St. Bartholomew's Hospital.—Res. H.S. £250. H.P. £200.
St. Mary's Hospital, Paddington, W.—Cas. Phys. £100.
Salford Royal Hospital.—Cas. H.S. £150.
Sheffield Royal Hospital.—Asst. Cas. O. £150.
Sydney University, New South Wales, Australia.—Chair of Psychiatry. £1100.
Wakefield, Clayton Hospital.—H.S. £225.
West Derby Union.—Asst. Res. M.O. at Walton Institution, Rice-Lane. £250.
Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £350.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of the following vacant appointments: Dunkeld (Perth), Somercotes (Lincoln).

Births, Marriages, and Deaths.

BIRTHS.

MELHUISH.—On August 8th, at Grove-road, Wrexham, the wife of Dr. T. W. Melhuish, of a son.

TOOGOOD.—On August 9th, at Liskerret, Liskeard, Cornwall, the wife of Sherman Toogood, M.A. Oxon., M.R.C.S., L.R.C.P., of a daughter.

WALLIS.—On August 13th, at Townshend-road, N.W., the wife of Dr. R. L. Mackenzie Wallis, of a daughter.

MARRIAGES.

BRIGGS—COOPER.—On August 4th, at the Parish Church, Bramhall, Christopher Duffield Briggs, M.R.C.S., of Wigston, Leicester, to Catherine Rosa, widow of J. T. Cooper.

DEATHS.

BULL.—On August 14th, at St. Oswald's House, Stony Stratford, William Henry Bull, Colonel, A.M.S. (T.), K.H.S., V.D., D.L., F.R.C.S. Edin., aged 69.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, August 22nd.—12 noon, Dr. S. Pinchin: Diseases of the Heart. 2 P.M., Mr. MacDonald: Surgical Out-patients. Mr. Simmonds: Visit to Surgical Wards. 4.30 P.M., Lecture:—Dr. Paterson: Deficiency Diseases.

TUESDAY.—2 P.M., Dr. Burrell: Medical Out-patients. Mr. Banks Davis; Diseases of the Throat, Nose and Ear. 2.30 P.M., Mr. Addison: Visit to Surgical Wards. 4.30 P.M., Lecture:—Dr. Burnford: Clinical Medicine (II.).

WEDNESDAY.—10 A.M., Mr. MacDonald: Genito-Urinary Department. 12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen. 2 P.M., Mr. Addison: Operations. Mr. Gibb: Eye Department. 4.30 P.M., Lecture:—Mr. Gibb: Ulceration of the Cornea (II.).

THURSDAY.—11.30 A.M., Obstetrical Registrar: Gynæcological Demonstration. 2 P.M., Dr. S. Pinchin: Medical Out-patients Mr. Simmonds: Orthopædic Department. 4.30 P.M., Lecture:—Mr. Simmonds: Surgical Emergencies (II.).

FRIDAY.—10 A.M., Mr. D. Buxton: Dental Department. 12.15 P.M., Dr. Burnford: Applied Pathology. 2 P.M., Dr. Pernet: Skin Department. 2.30 P.M., Dr. Pritchard: Demonstration of Cases. (Medical Wards.)

SATURDAY.—10 A.M., Dr. Burnford: Visit to Medical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients.

Daily:—10 A.M., Visit of Post-Graduates to Wards. 2 P.M., In-patient, Out-patient Clinics and Operations.

INDEX TO "THE LANCET," VOL. I., 1921.

THE Index and Title-page to Vol. I., 1921, which was completed with the issue of June 25th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1 and 2, Bedford-street, Strand, W.C.2.

THE LANCET: SUBSCRIPTION RATES.

Forty-two benign tumours: Lipoma, fibroma, fibro-myoma chondroma, osteoma, goundou, papilloma, polypi, adenoma of thyroid.

Five locally malignant tumours: Endothelioma (1), submaxillary, parotid, &c.; epithelial odontome (1) in coast native.

Three malignant tumours: Sarcoma of skull in coast native, 1; of femur, 1; of humerus, 1. Carcinoma, no cases seen among gynæcological work, though chronic endometritis very common.

Colleagues working in the Southern Provinces of Nigeria have told me that carcinoma, although not common, does occur.—I am, Sir, yours faithfully,

W. B. JOHNSON,
July 9th, 1921. West African Medical Staff.

UNIVERSITIES' LIBRARY FOR CENTRAL EUROPE.

To the Editor of THE LANCET.

SIR,—May I plead in your columns for the needs of the Universities' Library for Central Europe, which has just completed the first year of its work? Owing to the state of the foreign exchanges, English books are practically unobtainable in many parts of the Continent. The Universities' Library has been formed in order to supply, at any rate to some extent, the more pressing needs of continental universities for books and periodicals in every department of art and science. The library is supported entirely by voluntary donations of money and books. It has centres in Austria, Czecho-Slovakia, Hungary, Germany, Poland, Esthonia, Finland and Roumania, and from all of these requests for specific works in English have been received, amounting in all to more than 20,000 titles. Information as to the requirements of any particular centre will gladly be sent on application.

A representative who has recently visited the Continent reports an intense desire on the part of foreign universities to obtain English periodicals and books, as also a sincere wish on their part to establish contact with the intellectual world outside. Most people have books for which they have themselves little or no further use, but which would be highly valued in Central Europe. If your readers would be good enough to look on their bookshelves and take out those volumes which they think they could do without, even at some sacrifice to themselves, and would present them to the Universities' Library, they would help directly in relieving this intellectual distress. Donations of money are also greatly needed.

Mr. B. M. Headicar, librarian to the London School of Economics and Political Science, Clare Market, Kingsway, W.C. 2, is acting as secretary for the Universities' Library for Central Europe, and will gladly supply any information or forward any books or periodicals which are sent to him.

I am, Sir, yours faithfully,
JANET E. LANE-CLAYPON,
August 6th, 1921. Member of the Executive Committee.

ZINC ELECTROLYSIS FOR ENLARGED TONSILS.

To the Editor of THE LANCET.

SIR,—In an annotation in your issue of August 6th there is a reference to the treatment of enlarged tonsils by X rays. May I mention as another procedure zinc electrolysis of the base of the tonsil. This is done by transfixing the base with a fork with five or six zinc-coated prongs. The fork replaces the blade in a Mackenzie's guillotine, which is carefully insulated by painting with enamel. The fork is attached to the positive terminal of a rheostat, while the negative electrode makes contact with the tonsil in its mesial part. One application of a current of 200 milliampères for three minutes is sufficient to cause destruction of the tonsil, which sloughs away without hæmorrhage and without inflammation.

I am, Sir, yours faithfully,
Devonshire-place, W., August 11th. A. R. FRIEL, M.D.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Poison Antidotes Bill.

THE text has been published of the Poison Antidotes Bill. The measure consists of three clauses. Clause 1 provides that "where any poison is sold by retail which under any Act or order thereunder is required to be labelled 'Poison' there shall be printed on or attached to the receptacle containing such poison a description of an antidote or antidotes, with the usual dose or doses thereof." Clause 2 states that where any person sells any such poison "without the receptacle containing the same having a description and the usual dose of the antidote thereof printed or labelled thereon he shall be liable on conviction before a court of summary jurisdiction to a penalty for each offence not exceeding five pounds." Clause 3 provides that the Act is not to apply to Ireland.

HOUSE OF LORDS.

MONDAY, AUGUST 15TH.

Criminal Law Amendment Bill.

The House considered the Commons' amendments to the Criminal Law Amendment Bill. The Commons' amendment providing for the insertion of a new clause, making any act of gross indecency between female persons a misdemeanour, was negatived. Several other Commons' amendments were agreed to, including that giving power for the deportation of aliens for procuration. The amendment giving a judge power to order the trial referring to a charge of alleged incest to be heard in camera was negatived.

Licensing (No. 2) Bill.

The Licensing (No. 2) Bill was read a third time and passed.

War Pensions Bill.

The War Pensions Bill was read a third time and passed.

HOUSE OF COMMONS.

TUESDAY, AUGUST 9TH.

Travelling Grants to Panel Practitioners.

Mr. LAMBERT asked the Minister of Health the terms of the regulations under which grants were made to medical men by the Insurance Acts for mileage and travelling.—Sir A. MOND replied: I am sending the hon. Member a copy of the Regulations from which he will see that a Central Mileage Fund is constituted, into which the sums available for mileage are paid (Article 19), that a committee, known as the Distribution Committee, consisting of insurance practitioners and other persons, reports to me as to the basis on which the sums in the Central Mileage Fund should be distributed amongst insurance committee areas (Article 20), and that the sums allocated to each area after consideration of that Report are distributed amongst the practitioners in accordance with a scheme prepared jointly by the local panel committee and the insurance committee, which is subject to my approval (Article 21).

Overcrowded Areas.

Mr. TREVELYAN THOMSON asked the Minister of Health if he was aware that it was stated at the recent international conference on tuberculosis that improved sanitation and adequate housing accommodation were amongst the most important means that could be adopted for reducing tuberculosis; and, if this was so, in the interests of economy, would his department sanction the building of more houses in those districts which were badly overcrowded, and where labour and materials were available for more houses than had at present been sanctioned.—Sir A. MOND replied: In so far as it is possible to sanction the erection of further houses within the limitations of the Government's housing scheme, which have been laid down, I shall certainly do what I can to meet the needs of the more seriously overcrowded areas.

WEDNESDAY, AUGUST 10TH.

Naval Hospital, Plymouth.

Sir CLEMENT KINLOCH-COOKE asked the Financial Secretary to the Admiralty whether he was now in a position to state what steps had been taken to improve the accommodation for the sick-berth staff at the Royal Naval Hospital, Plymouth.—Mr. AMERY replied: It has been decided to construct new quarters for the sick-berth staff at the Royal Naval Hospital, Plymouth, as soon as financial conditions permit.

Service Grants to London Voluntary Hospitals.

Mr. GILBERT asked the Minister of Health what were the amounts paid in the years 1914 to 1919, respectively, as grants in aid to the London voluntary hospitals in con

Of the 94 private patients provided for in private dwellings, with the sanction of the Board, on Jan. 1st. 1921, there were 32 in houses possessing special licences for the reception of not more than 4 patients, and 62 in houses which, having only one patient, required no licence. All pauper patients, wherever placed, come upon the register of the Board; the number provided for in private dwellings on the above date was 2030. All lunatics and mental defectives were visited by officers of the Board, many receiving two visits during the year. The standard of care continues to be satisfactory.

Suggested Reforms.

A reform in terminology is strongly urged in the report; the Board are of the opinion that the terms "lunacy" and "lunatic" should be abolished, and that for the designation "asylum" should be substituted that of "mental hospital"; this change, the Board are convinced, would be welcomed by the great majority of those concerned with the administration of institutions for the insane, and they regret the necessity of their own employment of the statutory terminology in the report. Furthermore, about 80 per cent. of the pauper patients in Scottish asylums do not come from the pauper class and would not have become paupers except for the incidence of insanity; the injustice of the designation leads the Board to advocate its avoidance in future legislation on the subject. In the light of the success which has attended the establishment in 1890 by the Glasgow Parish Council of observation wards for patients with incipient forms of mental disease, it is recommended in the report that legislation be framed for legalising these clinics, for establishing them in suitable centres, with at least one in connexion with every medical school, for their use by all classes of the community which require them, and for their support by local authorities. The Board have reason to believe that the provisions relating to the six months' certificate are widely disregarded—i.e., that the cases of patients resident for more than six months in private dwellings and requiring compulsory restraint of some kind are not brought to the notice of the Board, the members of which body now consider that houses used for the purpose should be sanctioned and approved by them, and all names of patients sent to them. The terms of admission of voluntary patients are stated to require substantial amendment. In some of the larger asylums nearly 50 per cent. of all private patients paying higher rates of board are admitted as voluntary inmates; many of them being obviously insane, their reception is a contravention of the terms of the statute. Further, a certain number have, in course of time, to be certified and remain as certified patients in the asylum. It is suggested that the statute be amended to secure more effective restriction of the employment of this section to those persons whom it was designed to benefit, as well as a periodic review of the mental condition of all voluntary inmates in asylums; otherwise there appears to be no alternative except to reconsider the present basis of the medical certification of the insane. As the law now stands there is no provision for any but the more wealthy class of patients submitting themselves for treatment as voluntary patients. It is recommended that persons unable to pay for their own maintenance in asylums, and suitable for voluntary treatment, should be provided for in this respect by the local authority as if they were certified patients. With reference to pathological laboratories, the economical advantages of the central laboratories is emphasised, and it is stated that there is no necessity to appoint an assistant medical officer as pathologist to any individual asylum.

Expenditure on Pauper Lunatics.

The expenditure of local authorities on the maintenance of pauper lunatics for the year ending May 15th, 1920, was as follows:—For maintenance and other expenses of 17,481 pauper lunatics under care for longer or shorter periods during the year, in asylums, lunatic wards of poorhouses, and private dwellings, a total sum of £617,800 was paid. Of this expenditure £38,113 was repaid by relatives and others, and £115,703 was contributed from the local taxation account. The net expenditure by local authorities on the maintenance of patients was thus £463,984, which is £51,129 more than the expenditure of last year. As regards asylums, the average cost per head is 16*s.* 8*d.* weekly, or £43 6*s.* 8*d.* per annum; in licensed wards of poorhouses the cost is 15*s.* 11*d.* weekly, or £41 7*s.* 8*d.* per annum; as regards private dwellings, the average cost is 10*s.* 10*d.* weekly, or £28 3*s.* 4*d.* per annum.

HOME LABOUR AND INSANITY.

A CORRESPONDENT writes: There are 42 males and 80 females in the Haywards Heath Mental Hospital chargeable to the parish of Eastbourne, and the fact that there are nearly twice as many females as males has led to an interesting suggestion by the members of the asylum visiting committee of the board of guardians. In their report presented to the guardians on August 12th, the committee state that there was little doubt that the stress and strain of the endeavour of many women to run their home establishments are so heavy and troublesome that they succumb. "This," the report continues, "is a point which should be carefully considered by the Women's Institutes, as it is having a very great effect on the social life of the people. Search for all labour-saving devices must be continued and every endeavour made to induce children to think less of their own comfort and offer their help and assistance to the mothers or housekeepers of the family circle." The committee on the occasion of their visit found not one of the 42 males in bed, most of the latter being cases of a chronic character.

THE NEEDS OF KING'S COLLEGE HOSPITAL.

King's College Hospital is faced with a debt of some £100,000, and as a consequence half the 388 beds ordinarily placed at the disposal of the sick poor of South London and surrounding districts have been closed. The committee of management in the special effort which they have been making to arouse greater interest in the hospital and its work with a view to raising, not only sufficient funds to liquidate the debt but to enable them to reopen seven closed wards, have been greatly assisted by a gift of eight Roneo duplicators, to be used in the printing of letters of appeal and other printed matter, thereby saving the hospital a considerable sum. It is hoped that this gift from Messrs. Roneo may be an incentive to other firms to offer gifts either in money or in kind.

OPERATION FOR RHINOPHYMA.

IN the *Scalpel* for July 30th Dr. Fallas, of Brussels, describes three cases of rhinophyma in each of which he was able to restore to the patient his former normal appearance. The instructive element in his paper is the advantage he has found in the use of the thermo-cautery instead of the knife. In the first case, indeed, he began by a cutting operation, but was compelled to resort to the cautery on account of excessive bleeding. A necrosis of the right ala nasi in this case called for a subsequent plastic operation. In the remaining two cases Dr. Fallas used the thermo-cautery only. The operations were bloodless and if one may judge from the photographs published they were also completely successful. No grafting was found to be necessary.

"ERSATZ" LEATHER.

AN action in the German courts is to be noted in which damages were recovered against a German hatter by one of his customers, who had suffered from pain in his head after wearing one of the defendant's hats for a short time. His symptoms, whatever they may have been, were ascribed by the evidence to the composition of the band of the hat which was of artificial leather, or leather substitute, into the composition of which sulphuric acid entered. The court held that the hatter was bound to discover whether his goods were likely to be injurious to his customers; in other words, that he warranted them fit for their intended use. British importers of goods of this kind will no doubt accept the case as a warning to be careful as to the nature of the material purchased.

REST AND HELP FOR HOSPITAL NURSES.

To the Editor of THE LANCET.

SIR,—In your kindness you have allowed me to appeal for years past for contributions towards the Necessitous Ladies' Holiday and General Fund, and I venture once again to ask the charity of your readers, for whose generosity in the past I could never be grateful enough. The poor ladies are suffering pitifully now through the difficulty of obtaining work. Hospital nurses who have broken down, journalists, musicians, artists, actresses, discharged government clerks, and companions, many of whom, through age and infirmity, unable to obtain any sort of work, are left behind in the city in the summer months, exposed to the privations attendant on poverty.

The Fund also supplies food, medicine, and clothing, and comforts that are even more urgently needed than rest or change of air. Faced with the high cost of living on their tiny incomes, many are in daily anxiety.

I plead, then, for the old, the sick, and helpless. All contributions sent to the following address will be gratefully acknowledged and distributed among hospital nurses who have broken down.—I am, Sir, yours faithfully,

CONSTANCE BEERBOHM (Miss),
Treasurer.

40, Upper Berkeley-street, London, W. 1.

MR. ALEXANDER GRAY, M.A., head of the Approved Society Branch of the Insurance Department, Ministry of Health, has been appointed to the new Jaffrey Chair of Political Economy at the University of Aberdeen.

Medical News.

Joint Council of the Order of St. John and the British Red Cross.—The first report of the Joint Council of the Order of St. John of Jerusalem in England and the British Red Cross Society, covering the period from Sept. 4th, 1919, to March 31st, 1921, and including a statement of accounts, has just been issued. The departmental reports cover the subjects of the auxiliary hospital for officers, the central work rooms, the Emergency Help Committee, the Home Service Ambulance Committee (with map), the Hospital Services, the Joint V.A.D. Central Committee and V.A.D. Scholarship Department, the Museums Subcommittee, the Trained Nurses, and the departments dealing with organisation and appeals, personnel and medals, provisional limbs, and stores. Three appendices contain the Hospital Library report, the scheme of the County Joint Committee organisations, and a memorandum for use in the establishment of Medical Supply Depôts.

A Conference on Economic Recovery and World Peace, organised by the Fight the Famine Council for Economic Reconstruction and the Peace Society, will be held in the Caxton Hall, Westminster, from Oct. 11th to 14th.

The Voluntary Hospitals Commission continue to receive numerous applications from individual hospitals and, to avoid misunderstanding, they are anxious to make it known that grants will only be made on the recommendation in London of King Edward's Fund, or in the provinces of the local Voluntary Hospitals Committees. Steps are now being taken in coöperation with county and county borough councils to establish these local Committees; and any inquiry as to whether a Committee has already been appointed for a particular area should be addressed to the clerk to the county council. Hospitals are asked to defer their applications until the local Hospitals Committee has been appointed.

West Indian Medical Conference.—The first of what may well prove to be a series of helpful hygienic conferences was held last month at Demerara, British Guiana, the Administrator, Hon. C. Clementi, presiding. Prof. R. T. Leiper and Dr. J. Anderson attended on behalf of the Filariasis Commission of the London School of Tropical Medicine; Dr. E. P. Minett, Government medical officer of health, acted as secretary, and a number of medical delegates were present from Trinidad, Barbados, St. Lucia, Jamaica, Surinam, Grenada, and elsewhere. In his opening address the Administrator emphasised the sanitary difficulties of the only area yet colonised in British Guiana, which he described as a partially reclaimed swamp some four feet below the level of high spring tides.

The People's League of Health.—The first Travelling Scholarship Prize awarded by the People's League of Health has been won by Mrs. M. C. D. Walters, C.M.B., M.R.San.I. The award is in connexion with the Sims Woodhead series of constructive educational health lectures delivered during the spring at Morley Hall, George-street, Hanover-square, by the League. Mrs. Walters, who during the war worked in the maternity hostels for Belgian women, is shortly to visit Belgium, and will spend a week in Brussels, where arrangements have been made for her to inspect the health centres of the city, upon which she will report to the League. The second course of the Sims Woodhead Lectures will commence in October. The fee is 10s. for the course, and 5s. entrance fee for the examination with which the Travelling Scholarship Prize is connected. Applications should be made to Hon. Organiser, the People's League of Health, 7, Hanover-square, London, W. 1.

North-East London Post-Graduate College.—A special post-graduate course will be held at the Prince of Wales's General Hospital, Tottenham, N., from Sept. 26th to Oct. 8th. It will include practical demonstration on clinical and laboratory methods each morning, demonstrations on groups of selected cases, general hospital work, and a clinical lecture each afternoon. Lectures will be given by Mr. C. J. Bond, of Leicester, on "Latent Infections"; Mr. James Berry on "The Diagnosis of Thyroid Swellings"; Colonel L. W. Harrison on "The Routine Treatment of Syphilis and Tests of Cure in Gonorrhœa and Syphilis"; Colonel W. Byam on "The Invalid from the Tropics"; Dr. Arthur Giles on "Sterility"; Mr. H. D. Gillies on "Plastic Surgery"; and Sir W. H. Willcox on "Diabetes." Practical demonstrations will also be given in associated special hospitals. Luncheon will be obtainable in the neighbourhood and tea will be provided each day in the hospital. A syllabus will be issued in due course, and further information may be obtained from the Dean.

The Wellcome Historical Medical Museum will be closed for cleaning and decorating during the month of September.

Dr. H. E. Cuff, who lost his life on the Norfolk coast on August 15th in an unsuccessful attempt to rescue two daughters from drowning, was principal medical officer to the Metropolitan Asylums Board and author of books on nursing.

Essex County Tuberculosis Scheme.—Conferences between representatives of the Essex Local Medical and Panel Committees, the Essex Insurance Committee, and the Essex County Council, with a view to securing closer coöperation between the general practitioner and the tuberculosis officer in combating tuberculosis, have resulted in an amended scheme which comes into force on Oct. 1st. This scheme, which has received the approval of the Ministry of Health, aims at making the dispensary a consulting centre and not a centre for symptomatic treatment. This being so, the local medical and panel committees have undertaken to act in full coöperation with the tuberculosis officer in carrying out the revised scheme, and to do their utmost to prevail upon other members of the profession to do likewise. The need is recognised for strong support from various sections of the public if the care and treatment of tuberculous cases are to be really effective. To grapple with the factors of environment, food, nature of work, wages, and the ever-present responsibilities of dependants, Care Associations have been established in certain districts, and will be extended when opportunity affords. A circular issued by the chief tuberculosis officer to all medical practitioners in the county gives a convenient summary of existing facilities.

Training of Nurses at Leeds—Reference was recently made in these columns to the proposed diploma in nursing at the University of Leeds; for many years the question of training in nursing at the Union Infirmaries of the city and of some of the surrounding districts has also engaged the attention of the authorities. At the Union Infirmary in Beckett-street Dr. James Allan, who has held the post of medical superintendent for about 40 years, has always regarded it as a part of his duty to instruct the nurses, and some 25 years ago he systematised his courses of instruction; the independent medical man who acts as examiner has just presented his twenty-sixth annual report to the guardians. He describes the general education of the candidates as of a satisfactory character; their knowledge has been sound, and in some cases has attained to a really high standard. The latest examination was conducted by means of written questions, together with a separate viva voce examination of each candidate in the presence of the medical superintendent and of the matron. Of late years the number of candidates has sometimes reached 30; the total number who have presented themselves for examination during the operation of the scheme is 455. The Hunslet guardians and the Barnsley guardians have made use of the same scheme for some years, with the assistance of the same examiner, who has also acted for the Fever Nurses' Association in respect of the City Hospital at Seacroft. There is no doubt that the standard of knowledge and the character of the nursing have improved under these conditions.

County Health Reform in Ireland.—An Irish correspondent writes: For some months past there have been movements in several Irish counties to bring about a unification of county health services. The county council has in each case been acting in isolation from the Local Government Board and in harmony with the local government department of Dail Earann. Last week the county council of County Clare published the details of a careful scheme which appears to be based mainly on the proposals put forward in the report of the Irish Public Health Council. The scheme recommends that the county be a unit, with a portion of Limerick incorporated, and that all public health services be coördinated and administered by a single body, to be known as the County Board of Health, with authority over the medical staff, nursing staff and health inspectors, and having control of home assistance. The Board of Health will consist of 30 members—county councillors, chairman of rural and urban councils, members nominated by the county council, representatives of the county insurance committee and of the county medical association. The report provides for five public health institutions—viz., a mental hospital, a county central home (Ennis workhouse) for aged and chronic hospital cases and the harmless insane with a detached portion for tuberculosis cases, a county nursery, four district hospitals, and an inter-county sanatorium. The scheme is, no doubt, good in itself, but one feels that it would be wiser to wait until some legislative body is in a position to deal with the health services of Ireland as a whole.

addition to the universities and schools of medicine there are many institutions where medical study may be commenced. Applications for special exceptions are dealt with by the Students' Registration Committee, which reports all such cases to the Council.

Regulations for Maintenance of Register of Medical Students.

The following examinations have been approved by the Council:—(*a*) The final examinations for the degrees in Arts and Science of any University of the United Kingdom or of the British Dominions. (*b*) All examinations which are accepted for Matriculation in the Faculties of Arts or Pure Science in any one of the Universities of Great Britain or in the Queen's University of Belfast. (*c*) All examinations not included under the foregoing section (*b*), which are accepted for Matriculation in the Faculty of Medicine in any one of the Universities of the United Kingdom of Great Britain and Ireland provided the examination is completed at not more than two periods of examination, and that the pass-certificate (or certificates) includes English, Mathematics, Latin (or Greek or Hebrew), and at least one other subject named in the following list:—Latin, Greek, Hebrew, Arabic, Persian, French, German, Spanish, Italian, Russian, or any approved modern language. (*d*) The Council may grant special recognition to the following examinations not included under the foregoing sections (*a*), (*b*), and (*c*):—(1) The final examinations for the degrees in Arts and Science of any specially recognised Foreign University. (2) Examinations conducted by approved Examining Bodies within the United Kingdom under the provisions set forth in the foregoing section (*c*). (3) Examinations conducted by approved Examining Bodies out of the United Kingdom under the provisions set forth in the foregoing section (*c*), and under such other conditions as the Council may impose in each case.

List of Bodies whose Examinations are accepted under the Foregoing Regulations.

I. *Examinations in Great Britain.*

(1) The Matriculation Examinations in the Faculties of Arts and Science of, and all examinations accepted in lieu thereof by, the following Universities: Oxford (including Responsions and Moderations), Cambridge (including the Previous Examination and the General Examination), Durham, London, Manchester, Birmingham, Liverpool, Leeds, Sheffield, Bristol, Wales, Edinburgh, Glasgow, Aberdeen, St. Andrews. These examinations are accepted subject to the conditions set forth under Section 2 (*b*) above. (2) The Preliminary Examinations in the Faculty of Medicine of, and all examinations accepted in lieu thereof by, the Universities of Durham, Edinburgh, Glasgow, Aberdeen, St. Andrews. These examinations are accepted subject to the conditions of Section 2 (*c*) above. (3) Specially recognised Examinations conducted by approved bodies.

The following Schools Examinations have been recognised by the English Board of Education and are accepted by the General Medical Council under the conditions noted below.

AS FIRST EXAMINATIONS.

1. School Certificate Examination of the Oxford and Cambridge Schools Examination Board.
2. Senior Local Examination of the Oxford Delegacy for Local Examinations.
3. Senior Local Examination of the Cambridge Local Examinations and Lectures Syndicate.
4. School Certificate Examination of the University of Bristol.
5. First School Certificate Examination of the University of Durham.
6. General School Examination of the University of London.
7. School Certificate Examination of the Northern Universities Joint Matriculation Board.

AS SECOND EXAMINATIONS.

8. Higher Certificate Examination of the Oxford and Cambridge Schools Examination Board.
9. Higher School Certificate Examination of the Oxford Delegacy for Local Examinations.
10. Higher School Certificate Examination of the Cambridge Local Examinations and Lectures Syndicate.
11. Higher School Certificate Examination of the University of Bristol.
12. Higher Certificate Examination of the University of Durham.
13. Higher School Certificate Examination of the University of London.
14. Higher Certificate Examination of the Northern Universities Joint Matriculation Board.

(A) The First Schools Examination Certificate is accepted, provided it shows either (*a*) that English and mathematics have been passed "with credit," or (*b*) that English and a language other than English have been passed "with credit"; and also that mathematics has been passed on a "sufficient" standard. (The certificate under (*b*) must show by an explicit attestation of the examining authority that mathematics has been passed on a "sufficient" standard.)

(B) A First Schools Examination Certificate which does not fulfil one or more of the foregoing conditions is accepted, provided it is supplemented either (i.) by further Schools Examination Certificates obtained subsequently which fulfil (*a*) or (*b*); or (ii.) by certificates obtained at the Second (Higher) Schools Examination, which show that the deficient subjects (English, another language, mathematics, as the case may be) have been passed (whether as "full" or as "subsidiary" subjects) at the Second Schools Examination.

Other Certificates accepted under Clause 2 (*b*). Scottish Education Department: Leaving Certificates.

Other certificates accepted under Clause 2 (*c*). Scottish Education Department: Intermediate Certificate. Central Welsh Board: Senior Certificate. University of St. Andrews: Final Examination for Diploma of L.L.A. College of Preceptors: Senior Certificate: Preliminary Examination for Medical Students Certificate. Educational Institute of Scotland: Preliminary Medical Examination Certificate.

II. *Irish Examinations.*

University of Dublin: Matriculation Examination: (*a*) Junior Freshman Term Examination (exclusive of Trigonometry); (*b*) Special Preliminary Examination to be held in March, the standard and subjects of which shall be those of a Junior Freshman Examination (exclusive of Trigonometry); (*c*) Junior Exhibition Examination on obtaining marks of sufficient merit in the subjects of (*a*) or (*b*); (*d*) Examinations for the First, Second, Third, or Fourth Year in Arts. (Certificate to be signed in the approved form by the Medical Registrar of the University.) Queen's University of Belfast: Matriculation Examination. National University of Ireland: Matriculation Examination. Intermediate Education Board of Ireland: Middle Grade Examination, with Honours in three subjects: Senior Grade Examination. Royal Colleges of Physicians and Surgeons in Ireland: Preliminary Examination. These Examinations are accepted subject to the conditions set forth in Section 2 (*c*) above.

The remainder of the curriculum, though all under the supervision of the Council, is in detail in the hands of the various degree- and diploma-granting bodies whose representatives are members of the General Medical Council. In the next pages we give the regulations of the various examining bodies, but it must always be remembered that the examinations are under the supervision of the General Medical Council, who visit the various centres in turn and closely inspect the procedure.

III. *Examinations Held Out of the United Kingdom.*

Every Certificate from Indian, Colonial, and Foreign Universities and Colleges must contain evidence that the Examination has been conducted by or under the authority of the Body granting it, must include all the subjects required by the General Medical Council, and must state that all the subjects of Examination have been passed in at not more than two examinations; copies of the form of the required Certificate are supplied by the Registrar of the Council for the purpose. In the case of Natives of India or other Oriental countries whose vernacular is other than English an Examination in a Classical Oriental Language—e.g., Sanskrit, Arabic, Chinese—may be accepted instead of an Examination in Latin. The Abiturienten-Examen of the Gymnasia and Real Schulen on the continent and the examinations entitling to the French diplomas of Bachelier ès Lettres and Bachelier ès Sciences and other corresponding Entrance Examinations to the Universities in Europe are recognised by the General Medical Council.

These examinations are accepted subject to the conditions set forth in Section 2 (*c*) above.

Further particulars are given in the Students' Regulations, which can be obtained at the offices of the Council, price 1*s.* 2*d.*

Registration of Medical Practitioners.

Under the provisions of the Medical Act, 1858, any person possessing one or other of the medical qualifications enumerated in the schedule to the Act is entitled to registration by the General Medical Council on producing to the registrar of a Branch Council proper

Notes, Short Comments, and Answers to Correspondents.

SOVIET RUSSIA AND PROSTITUTION.

THE flood of refugees from Russia may not only bring cholera, typhus, or plague with them, but may also accentuate the prevalence of venereal disease. At the Third Congress of the Women's Sections of the Russian Communist Party, Mme. Alexandra Kollontay, one of the leading women of Soviet Russia, made a forcible speech on the subject of prostitution. A first edition of 40,000 copies of this speech was at once printed and widely circulated. It was then translated, and a first instalment is published in the August number of *Soviet Russia*, the New York organ of the Bolshevist party. From this it appears that the Bolshevist Council of the People's Commissars, when it came into power, at once abolished all Tsarist legislation on prostitution; but no other measures have been substituted. Certain localities have, however, acted on their own initiative and without interference from the central Government. In one town disorderly houses are totally closed, while in another they are allowed openly to exist. In some districts prostitutes have been rigorously suppressed, sometimes even with the aid of the militia, and treated as criminals, while in other places they are not molested at all. The speaker expressed regret at the lack of popular fundamental principles on the question, and proceeded to define the meaning of prostitution in the terms of Bolshevism. It was "a phenomenon closely bound up with an income not earned by labour; it therefore flourished in the epoch of the rule of capitalism and private property." Soviet Russia consequently must abolish prostitution because it is a survival of the principle of private property; but, above all, because by selling herself, even if only temporarily, the prostitute "becomes a *deserter from work*." Because prostitutes do not contribute their share of productive social work they must be "mercilessly condemned."

Regard for public health only entered the question as a secondary consideration, but it was by no means overlooked. The speaker recognised that prostitution is one cause, but in no sense the only cause, of venereal disease. Defective hygiene, scarcity of plates, cups, towels, &c., frequently give rise to infection.

An Insight into Conditions in the War Areas.

Mme. Kollontay proceeded to paint an alarming picture of the spread of venereal disease in Russia, apart from prostitution; for instance, in the fruitful southern provinces, where civil war has been in progress, the male Cossack population has been driven out with the Whites, or has been scattered to the winds. Only women remained in the settlements; they had enough of everything, but there were no men. Red armies advanced and took the towns, the men were billeted out, and remained for weeks at a time. Free alliances resulted, having no similarity whatever with prostitution, since the women voluntarily associated with the men with no view to material gain; indeed the gain was on the other side, the women taking care of the Red soldiers, mending their clothes and giving them homes so long as the army remained in the settlement. In this way the settlements became infected with venereal disease. The same thing was repeated with cities and villages, which were taken by the Whites. A general contamination is constantly going on. The diseases are increasing and threaten to wipe out the entire unborn population.

Suggested Preventive Measures.

To combat this danger Mme. Kollontay urged the provision of a proper sexual education for the young, so that children might enter life armed with precise information. Then she continued to plead that the most precious moral weapon the worker could possess was the feeling of comradeship and solidarity between the sexes. The possible purchase of a woman must degrade such feeling; therefore, "from the standpoint of the new Communist morality which is in process of formation, of crystallisation, prostitution is intolerable and dangerous."

Meanwhile there is a steady increase of prostitution and its attendant diseases. It is to be hoped that, as Mme. Kollontay possesses great influence in Soviet Russia, the further instalment of her speech will suggest some practical measures calculated to be of immediate service.

PUBLIC HEALTH IN ASSAM: (1) KALA-AZAR; (2) VACCINATION.

IN continuation of his report on Sanitary Matters in Assam, noticed in these columns on Nov. 27th, 1920, Major T. McCombie Young, I.M.S., Sanitary Commissioner, has issued an interesting account of the measures undertaken for dealing with the serious epidemic of kala-azar in that province during 1919. The main principle has been, where circumstances rendered it practicable, to send subassistant surgeons on survey every year through any endemic area to observe the general activity of the disease, and to discover any individual villages in which hyper-endemic conditions may have appeared. In such cases the village is notified as an infected area and its inhabitants are removed, each family being classified as infected, contact, or free, and located in each group on separate sites: a subassistant surgeon is posted to treat the sick and to supervise the working of preventive regulations. In the Sibsagar district an attempt was made to discover and deal with every village in which even a single case of kala-azar existed, and experience indicates that had a clean sweep been made in the whole area in 1917 the outbreak might have been terminated earlier, "at the same outlay, but with considerable economy in the lives of persons who would have escaped the disease." The reality of site infection is considered to have been proved, and the only known remedy is evacuation. If the bed-bug is the carrier "we still want to know under what conditions in nature it becomes infective, and how it travels from village to village to originate new foci of infection."

The report on Vaccination in this province (also by Major Young) for the triennial period, 1917–18 to 1919–20, shows the considerable increase of 81,207 operations, as compared with those of the preceding three years, but this was almost entirely due to the inclusion of the Manipur State in the provincial statistics. The ratio of successful vaccinations to the total population rose from 43·74 per 1000 in 1917–18 to 52·97 in 1919–20; for which years the small-pox mortality fell from 0·59 to 0·20 per 1000. The lymph supplied from the vaccine depôt at Shillong was of excellent quality, the percentage of success being 95·71 in primary operations and 72·04 in revaccinations: glycerinated lymph only is used.

MENTAL HOSPITALS IN SCOTLAND: ANNUAL REPORT OF THE BOARD OF CONTROL.

THE General Board of Control for Scotland have published their seventh annual report on the condition and management of lunatic asylums and on the protection and control of mental defectives in Scotland. On Jan. 1st, 1921, there were in Scotland 17,806 insane persons (exclusive of insane persons maintained at home by their natural guardians) of whom the Board of Control had official cognisance; this number, which showed an increase of 226 on that of the previous year, included the inmates of training schools for imbecile children not certified under the Mental Deficiency Act, and inmates of the criminal lunatic department of Perth Prison. Of this total, 2981 were maintained from private sources, 14,752 by parochial rates, and 70 at the expense of the State. With reference to registered lunatics, there was a total increase of 233 (38 private patients, 195 pauper patients) on the previous year's figures, owing to an increase of the number in establishments by 317 and a decrease of the number in private dwellings by 111.

Admissions, Discharges, &c.

The total number of patients admitted to establishments under a sheriff's order, sanction of the Board, and other statutory authority, was 3873 (161 more than in 1919); this figure excludes admissions by transfer, of which there were 706, a high number explained by the reconversion of Renfrew District Asylum from a temporary war hospital. Of voluntary patients 313 were admitted to asylums in 1920. Discharges were as follows: 358 private patients, 970 pauper patients, discharged recovered; 221 private patients, 311 pauper patients, discharged unrecovered, all these figures being higher than in the preceding year. Deaths occurred of 281 private patients and 1202 pauper patients, the combined death-rate for patients in establishments being 10·1, as compared with 12·1 in 1919. The total reported number of accidents to patients was 103, 18 being fatal, of which 9 were suicides; cases of attempted suicide numbered 7.

Present Condition of Establishments.—Lunatics in Private Dwellings.

Establishments for the insane in Scotland comprise: (a) royal and district; (b) private and (c) parochial asylums; (d) lunatic wards of poorhouses; and (e) the department for criminal or State patients in Perth Prison. On account of the abnormal conditions now existing many difficulties have to be faced in connexion with the administration of institutions, a large percentage of inmates of which are hospital cases. Favourable comment is, however, made on the fact that, while economy is most carefully kept in view, the dietary is ample and varied. As a general rule, the management of these establishments reflects credit upon the officials, and almost without exception a satisfactory standard of efficiency would appear to be maintained. Similarly, favourable reports are given of the administration of the establishments for mental defectives.

Medicine, the Litchfield Lecturers in Medicine and Surgery, and the other physicians and surgeons. Instruction is also given in post-mortem work and Clinical Pathology in connexion with the courses in Pathology. Post-graduate courses will be held at the beginning of October.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1918 (both of which are published by the Clarendon Press); from the Regius Professor of Medicine; and from the Professors in the several departments of medical science.

UNIVERSITY OF OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) Clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. (4) Pathological demonstrations and instruction in post-mortem work are given by the Assistant Pathologist. Opportunities are offered to students who wish to act as surgical dressers and clerks. The hospital contains 210 beds.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms (three years) by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., if possible, before he comes into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield, the Matriculation Examination of the University of Birmingham, or by being a graduate of certain other Universities in the United Kingdom. He may then devote himself to medical study in the University, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing two Special Examinations for the ordinary B.A. degree, or an Honours degree in one of the Triposes. The Natural Sciences Tripos is taken most frequently, as some of the subjects are practically the same as those for the first and second M.B.

For the degree of *Bachelor of Medicine* (*M.B.*) five years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge till the student has passed the examination for Part I. of the Natural Sciences Tripos and the first and second examinations for M.B. Hospital practice and many of the requisite lectures may be attended in Cambridge, and some students remain to attend lectures and hospital practice until they have passed the second part of the second examination for M.B. The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for M.B. The *first* includes (1) Chemistry, (2) Physics, and (3) Elementary Biology. These parts may be taken together or separately. The *second* is divided into two parts—viz., (1) Human Anatomy and Physiology; and (2) Pharmacology and General Pathology. The *third* is also divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic.

Candidates who have passed both parts of the third M.B. examination are admitted to the registrable degree of *Bachelor of Surgery B.Ch.*) without separate examination and without keeping an Act.

The degree of *Doctor of Medicine* (*M.D.*) may be taken three years after that of M.B. or four years after that of M.A. The candidate is required to produce certificates of having been engaged in Medical Study for five years, and if an M.A., to pass the same examinations as are required for the degree of M.B. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools with *vivâ voce* examination; and a short extempore essay has to be written on a topic taken from the general subject of his thesis, whether it be Physiology, Pathology, Pharmacology, the Practice of Medicine, State Medicine, or the History of Medicine.

For the degree of *Master of Surgery* (*M.Ch.*) the candidate must have passed all the examinations for B.Ch., or, if he is an M.A., have obtained some other registrable qualification in surgery. He is required to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B.Ch.

Diplomas are granted in Public Health in Tropical Medicine in Medical Radiology and Electrology, and in Psychological Medicine. Candidates must hold a recognised medical qualification.

Women Students.—Increased facilities have been offered to students of Girton and Newnham Colleges, and they are admitted to the First and Second M.B. Examinations under certain conditions.

University Prize in Medicine.—The one University Prize in Medicine, the Raymond Horton Smith Prize (value £19), is awarded to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a tripos examination. Medical studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registrary, The Registry, Cambridge.

ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are given at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery is given in the wards and out-patients' rooms by the physicians and surgeons daily during the term time and vacations. The fee for pupilship is 3 guineas a term, 9 guineas a year, 12 guineas perpetual. Further information may be obtained from Dr. Aldren Wright.

UNIVERSITY OF LONDON.

The University of London was established by Royal Charter in 1836 as an examining and degree conferring body with affiliated colleges but no direct teaching functions. In 1900 it was reconstituted under the Act of Parliament, 1898, and became a teaching as well as an examining body. Many schools already existing became constituent colleges, including all the metropolitan medical schools. Lecturers were also appointed in special subjects.

LIBRARY

STUDENTS' GUIDE—SESSION 1921-1922.

THE scheme upon which the Students' Number of THE LANCET is constructed will make it easy, we hope, for all who consult it to find what they seek. The General Council of Medical Education and Registration is the controlling authority of all the medical education of the country, and its responsibility for the upkeep of the Medical Register and for the maintenance of the examination standard is first explained.

But the student has to be taught as well as examined, and as the systems under which instruction can be obtained do not conform to one pattern, the various curricula are described in detail, and under their respective headings the necessary information will be found concerning the facilities for medical study offered at the different teaching centres of the United Kingdom. The regulations for the examinations, both preliminary and professional, at these centres are set out so that the student desiring to obtain a medical degree from any university, or a diploma from any medical corporation, may ascertain the course of clinical instruction and the conditions under which submission for examination has to take place. The metropolitan medical schools and hospitals are grouped under the University of London, of which they are constituent bodies, although their educational opportunities are offered to other universities as well as to the medical corporations. A similar plan is adopted in dealing with the provincial universities, the hospitals in direct connexion with which are described with the universities; for though the hospitals may not be official schools of the universities, they supply an integral section of the teaching required by the graduates.

Upon securing degrees or diplomas admission to the Register follows, and greater education begins. The prudent young doctor already knows what he or she desires to make the next step, and there is a large range of choice displayed. The inducements to enter one of the Services should prevail more than they have done of recent years. An account is given of the conditions under which commissions can be obtained in the Navy, Army, Indian, and Air Force Medical Services, and in the Colonial Medical Service.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

POWERS, DUTIES, AND CONSTITUTION OF THE GENERAL MEDICAL COUNCIL.

THE powers and duties of the General Medical Council, or "General Council of Medical Education and Registration of the United Kingdom" to give the Council its full title, have been set out in detail in many previous Students' Numbers of THE LANCET. It is first a registering body: no person, even though his qualifications have been obtained, is a legally qualified medical practitioner unless his name appears on the Medical Register. Secondly, it is a standardising body, ensuring that the education of medical men is kept up to an efficient standard by scientific examination. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner adjudged guilty of conduct "infamous in a professional respect." Fourthly, to the Council is committed the codification of pharmaceutical remedies. The duties of the Council are thus primarily of a public nature, and its construction shows its fitness for its fourfold responsibilities.

The Council at present consists of 38 members, of whom, as will be seen by the annexed list, all but 11 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and six others are elected by the members of the medical profession as Direct Representatives.

President of the General Council: Sir Donald MacAlister. Members of the General Council: Sir Norman Moore, chosen by the Royal College of Physicians of London; Mr. Holburt Jacob Waring, F.R.C.S., Royal College of Surgeons of England; Dr. Benjamin Bloomfield Connolly, Apothecaries' Society of London; Mr. Arthur Thomson, F.R.C.S., University of Oxford; Mr. Frederick Gowland Hopkins, M.A., M.B., University of Cambridge; Dr. Robert Howden, University of Durham; Sir Sydney Russell-Wells, University of London; Dr. Henry Roy Dean, Victoria University of Manchester; Sir Harry Gilbert Barling, University of Birmingham; Dr. Richard Caton, University of Liverpool; Dr. Thomas Wardrop Griffith, University of Leeds; Mr. John Beresford Leathes, M.B., University of Sheffield; Sir Isambard Owen, University of Bristol; and Dr. David Hepburn, University of Wales. Dr. William Russell, chosen by the Royal College of Physicians of Edinburgh; Sir James Hodsdon, Royal College of Surgeons of Edinburgh; Dr. James Alexander Adams, Royal Faculty of Physicians and Surgeons of Glasgow; Dr. H. Harvey Littlejohn, University of Edinburgh; Sir Donald MacAlister, University of Glasgow; Dr. Matthew Hay, University of Aberdeen; and Dr. John Yule Mackay, University of St. Andrews. Sir John William Moore, chosen by the Royal College of Physicians of Ireland; Sir Arthur Gerald Chance, Royal College of Surgeons in Ireland; Dr. Edward Magennis, Apothecaries' Hall of Ireland; Dr. Andrew Francis Dixon, University of Dublin; Denis Joseph Coffey, M.B., National University of Ireland; and Mr. Thomas Sinclair, F.R.C.S., Queen's University of Belfast. Nominated by His Majesty, with the advice of his Privy Council: Sir Francis Henry Champneys, Sir George Newman, Mr. Norman G. Bennett, Dr. John Christie McVail, and Sir Edward Coey Bigger. Elected as Direct Representatives: Dr. J. A. MacDonald, Sir Thomas Jenner Verrall, Dr. Robert A. Bolam, Mr. E. B. Turner, Dr. Norman Walker, and Dr. Leonard Kidd. Treasurers of the General Council: Sir Norman Moore and Mr. Holburt J. Waring.

THE EDUCATIONAL CURRICULUM.

Professional Education.—The course of professional study after registration occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

Registration and Preliminary Examination of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—Every medical student should be registered in the manner prescribed by the Council. The registration of medical students is placed under the charge of the Branch Registrars. Every person desirous of being registered as a medical student should apply to the Branch Registrar of the division of the United Kingdom in which he is residing; and should produce or forward to the Branch Registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has attained the age of 16 years, and has commenced medical study at an institution approved by the Council. The Branch Registrar shall enter the applicant's name and other particulars in the Students' Register and shall give him a certificate of such registration. Each of the Branch Registrars shall supply to the several licensing bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The commencement of the course of professional study recognised by any of the qualifying bodies should not be reckoned as dating earlier than 15 days before the date of registration. In nation in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Mental Diseases; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. (except in branch 5) may transmit to the Registrar a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners the candidate may be exempted from a part or from the whole of the written examination in that subject.

Master in Surgery.—The examination for the degree of Master in Surgery takes place twice in each year and commences on the first Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches: (1) Surgery; (2) Dental Surgery; (3) Ophthalmology; (4) Laryngology, Otology and Rhinology. A thesis may be submitted as for M.D.

Fees.—Matriculation £2 12*s.* 6*d.* for each entry. at provincial examinations an additional local fee is charged. First examination for Medical Degrees: £6 6*s.* for each entry to the entire examination. For re-examination in one subject the fee is £2 2*s.* In the second examination, Part I. £2 2*s.*, repeated on each subsequent entry: Part II. £8 8*s.* for the whole examination. Third examination: £10 10*s.* for each entry to the whole examination. M.D. Examinavion: £21; for re-examination £10 10*s.* M.S. Examination: As for M.D.

Full details of the prescribed curricula of study and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Principal Officer, University of London, South Kensington, S.W.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley. It receives over 8000 in-patients annually and its out-patients and casualties amount to more than 75,000 annually. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electro-therapeutics and X Ray work. Surgical operations take place every day at 1.30 P.M. and Surgical consultations are held on Thursdays at the same hour. Medical consultations are held on Thursdays at 3.15 P.M. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical lectures on all special subjects are also given. Wholetime Clinical Units under Professors of Medicine and Surgery have been established.

Ten house physicians and ten house surgeons are appointed annually, and are provided with rooms and board by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and board and receive a salary of £80 a year. Three resident anæsthetists are appointed annually, and receive salaries of £120, £100, and £100 respectively, with rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. A residential college is attached to the hospital.

New Buildings.—The new buildings comprise residential quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. A new chemical laboratory has been added to the Medical School, and a laboratory devoted to instruction in Public Health. A second new block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, pathological histology, and pathological chemistry. *The Medical School Buildings* include three large lecture theatres, a large dissecting room, a spacious library (containing 13,000 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is the most complete in the kingdom. There are laboratories for chemistry, physiology, pharmacology, physics, public health, and biology, giving ample accommodation in every department.

Special Classes for the Primary and Final F.R.C.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. *Laboratory Instruction for the D.P.H.* is provided during the winter and summer sessions. Facilities for research work are afforded in the Clinical Units and the Laboratories of the pathological and other departments. The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range.

Scholarships given in aid of Medical Study.—At this school various Scholarships, prizes, &c., are given. For five of the Scholarships and the Exhibition—namely, (*a*), (*b*), two Entrance Scholarships of the respective values of £75 and £100; (*c*) Entrance Scholarship in Arts, £100; (*d*) Jeaffreson Exhibition, £50; and (*e*) Shuter Scholarship, £50—a full or University course at St. Bartholomew's Hospital is required. The awards of (*a*) and (*b*) are made after examination in selections from the subjects of Chemistry, Physics, Zoology, Botany, Physiology, and Anatomy; (*c*) and (*d*) are awarded after examination in Latin, Mathematics, and Greek or French or German; (*e*) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology. The remaining Scholarships and prizes are as follows:—Four Junior Scholarships—(*f*) No. 1, £30, Anatomy and Physiology; (*g*) No. 2, £20, Anatomy and Physiology; (*h*) No. 3. £25, Chemistry, Physics, and Biology; (*i*) No. 4, £15, Chemistry, Physics, and Biology; (*j*) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (*k*) Kirkes Scholarship, £30 and medal, Clinical Medicine; (*l*) and (*m*) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery; (*n*) Sir G. Burrows Prize, £10, Pathology; (*o*) Skynner Prize, 13 guineas, Regional and Morbid Anatomy; (*p*) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (*q*) Luther Holden Research Scholarship in Surgery, awarded by election, £105; and (*r*) Lawrence Research Scholarship and gold medal in Pathology, awarded by election, £115.

Information may be obtained on application to the Dean to the Medical School: Dr. T. W. Shore. The Warden of the College is Mr. R. M. Vick.

CHARING CROSS HOSPITAL.—The Hospital, to which the School is attached, contains 300 beds. Over 3000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated. There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Ear, Throat, Nose, and Teeth, for Orthopædic Cases, X Ray work, and for Electrical Examination and Treatment.

Appointments.—In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School. Medical, Surgical, and Obstetric Registrars to the Hospital are appointed annually. Six House Physicians, six House Surgeons, evidence of qualification. Registration entitles him, in the words of the Act of 1886 :—

---

[1] For Ancillary Metropolitan Medical Schools see p. 443.

> "...... To practise medicine, surgery, and midwifery in the United Kingdom, and (subject to any local law) in any other part of [Her] Majesty's dominions, and to recover in due course of law in respect of such practice any expenses, charges in respect of medicaments or other appliances, or any fees to which he may be entitled ......"

These qualifications are enumerated in the Medical Register, printed each year under the direction of the Council, and the course of study necessary to obtain each of them is duly set out in the succeeding pages.

A number of diplomas granted in British possessions and in certain foreign countries entitle the holder to registration in the colonial or foreign list respectively of the Medical Register, and therefore to practise medicine within the borders of the United Kingdom. Some account of these diplomas is given on p. 477 and following pages. It should, however, be carefully noted that, where any local registration is required for legal qualification, it is essential that, before registration in the United Kingdom, evidence should be produced of registration in the country, province, or state in which the qualification was obtained.

Officers of the Council.

Norman C. King, Registrar of the General Council and of the Branch Council for England, 44, Hallam-street, Portland-place, W. 1.—T. H. Graham, O.B.E., Registrar of the Branch Council for Scotland, 20, Queen-street, Edinburgh.—Richard J. E. Roe, Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin. All communications should be addressed to "The Registrar" and not by name.

THE MEDICAL EXAMINING BODIES AND SCHOOLS OF THE UNITED KINGDOM.

A GUIDE TO THE FACILITIES FOR OBTAINING THE VARIOUS MEDICAL DEGREES AND OTHER QUALIFICATIONS FOR THE BRITISH MEDICAL REGISTER.

I.—ENGLAND AND WALES.

THE UNIVERSITIES.

UNIVERSITY OF OXFORD.

THIS University confers two degrees in Medicine, those of *B.M.* and *D.M.*, two in Surgery, *B.Ch.* and *M.Ch.*, and diplomas in *Public Health*[1] *and Ophthalmology.*

Only Graduates in Arts of the University are eligible for the Medical and Surgical degrees. The most convenient course for the B.A. degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. To obtain the degrees of B.M. and B.Ch. the following examinations must be passed: 1. Preliminary subjects: Mechanics and Physics, Chemistry, Zoology, and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has satisfied the examiners in Part I. Chemistry in the Natural Science School; Human Physiology, unless he has obtained a First or Second Class in Animal Physiology in the Natural Science School; Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology. The First and Second Professional examinations are held in June and December. The first B.M. examination may be passed at any time after the Preliminary Scientific examinations. Anatomy and Physiology must be passed at the same time—Organic Chemistry may be taken separately.

At any time after passing the First Examination, the candidate can, on producing certificates, present himself for examination in the subjects of Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology; but cannot enter for examination in Medicine, Surgery and Midwifery until the eighteenth term from his matriculation, nor until a period of at least twenty-two months has elapsed from the date of passing the First B.M. Examination. He must take Medicine, Surgery and Midwifery at one and the same time.

Before admission to the Second B.M. Examination, the student must produce certificates of having attended laboratory courses in Pathology, Bacteriology and Pharmacology either in Oxford or in a recognised medical school. He must also produce certificates of having acted as Clinical Clerk and Dresser, each for six months, in a medical school approved by the University, of three months post-mortem clerking, of attendance on Labours, of instruction in Infectious Diseases and Ophthalmology, and of proficiency in vaccination and the administration of anæsthetics.

The degree of B.Ch. is granted with that of B.M. after passing the above examinations. The degree of D.M. is granted to Bachelors of Medicine of the University who have entered upon their thirtieth term from Matriculation, and have submitted a dissertation which is approved by the examiners for the B.M. degree whose subjects are dealt with therein and by Professors in the Faculty of Medicine. The degree of M.Ch. is granted after examinations to Bachelors of Surgery in the University who have entered upon their twenty-first term, and who are Members of the Surgical Staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for a period of six months. The examination, which includes Surgery, Surgical Anatomy and Pathology and Surgical Operations, is held annually in June, after the Second B.M. examination.

The examinations for the Diploma in Public Health[1] in two parts are held in Trinity and Michaelmas terms; that for the Diploma in Ophthalmology is held annually commencing on the third Monday in July. For the Diploma of Ophthalmology attendance at a course of instruction in Oxford, lasting two months, is obligatory. Candidates must be registered medical men, unless, being Bachelors or Doctors of Medicine of Universities outside the United Kingdom they have obtained special permission from the Board of the Faculty of Medicine.

Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for three years and of the annual value of £200. The examination is in Physiology, Pathology, and hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Radcliffe Library, University Museum. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially for research in some branch of medical science. The Theodore Williams Scholarships, each of the value of £50 a year for two years, are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A King's College Hospital Burney Yeo Scholarship of £80 is awarded each year. The Scholarships in Science which are offered by several Colleges are open to those who intend to pursue Medicine. The value of these scholarships is usually £80 a year for four years. There are also Medical Scholarships of the value of £100 a year at University College and at Pembroke College. The Welsh Memorial Prize for Anatomical drawing is awarded annually, and is of the value of about £10.

In addition to the University Lectures and classes the several Colleges provide their undergraduates with tuition for all examinations up to the B.A. degree.

In the Radcliffe Infirmary and County Hospital clinical instruction is given by the Regius Professor of candidates under 21 years of age, to be awarded either in Arts or in Science, according to the discretion of the Examiners, and to the percentage of the marks obtained; (e) three scholarships, one of £80, one of £75, and one of £35, for students under 25 years of age who have completed the curriculum for, or passed the examination in, Anatomy and Physiology for a medical degree in any University of the British Empire, and have not entered as students in any Metropolitan Medical School. Subjects: Any two of the following: Anatomy, Physiology, Pharmacology, General Pathology, Organic Chemistry.

---

[1] The regulations for the Diplomas in State and Tropical Medicine of the various Examining Bodies will be found on page 473.

In agreement with the practice of the Universities, an allowance will be made (1) for Military Service performed by candidates. the term " military service " meaning service in the Naval or Military Forces of His Majesty or of His Majesty's Allies during the war; or (2) in respect of other approved duties in connexion with national defence.

The Dean of the Medical School is Professor T. B. Johnston, from whom further information may be obtained.

UNIVERSITY OF LONDON: KING'S COLLEGE.—The medical department (Faculty of Medical Science) at this College only deals with Preliminary and Intermediate subjects, and instruction in these subjects is given in the College laboratories by university professors and their assistants to students entering the College directly and also to students of the following four hospital schools which prepare only for the final examinations—viz., King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital. The department is open to both men and women.

Fees.—(*a*) Entrance fee, £6. (*b*) Tuition fee of 12 guineas per term, or a composition fee of 35 guineas per annum if paid at the commencement of the session, or a composition fee of 100 guineas for the three years' course if paid at the commencement of the course. For prospectus and further information application should be made to the Dean of the Medical Faculty (Professor E. Barclay-Smith).

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The advanced subjects in the curriculum are dealt with at the Medical School attached to King's College Hospital, which is situated at Denmark Hill, S.E. 5. The hospital stands in the midst of a South London population, from which an immense amount of clinical material is forthcoming. During the past year there were 200,655 attendances in the out-patient and casualty departments. There are 400 beds available for in-patients, and provision will ultimately be made for 600 beds. There are special departments for Bacteriology, Children, Clinical Pathology, Dermatology, Gynæcology and Obstetrics, Laryngology, Massage, Neurology, Odontology, Ophthalmology, Orthopædics, Otology, Physicotherapy, Psychological Medicine, Radiology, Rhinology, and Urology, each in charge of a specialist and his staff. Clinics are also held in applied pharmacology, cardiology, and medical chemistry. The appointments open to students are those of clinical assistant to the special departments: medical, surgical, obstetric, and pathological tutorships; resident casualty officers: resident anæsthetist; bacteriologist; clinical pathologist; pathological registrar; and medical, surgical, and obstetric registrarships. Fifteen resident medical and surgical officers are appointed half-yearly.

Scholarships and Prizes.—(*a*) Two Warneford Scholarships, tenable for four years, £30 each per annum: (*b*) Sambrooke Scholarship, tenable for two years, £25 per annum; (*c*) Rabbeth Scholarship, £20; (*d*) Medical Entrance Scholarships, £50 (Anatomy and Physiology), and £50 (Pathology and Pharmacology) open to students who (1) propose to take a degree at any British University, and have passed their University examination in Biology, Chemistry, and Physics, and who (2) will become students at King's College Hospital from date of entering upon Scholarship; (*e*) Two Medical Entrance Scholarships, one in Arts and one in Science, £50 each, tenable for five years, successful candidates to study at King's College and King's College Hospital; (*f*) Three Medical Scholarships, £40 for fifth-year students, £20 for third-year students, and £20 for second-year students; (*g*) Three Sambrooke Registrarships, open to matriculated students who have filled certain appointments in hospital; (*h*) Carter Prize, £15, Botany; (*i*) Tanner Prize, £10, Obstetrics and Diseases of Women; (*j*) Todd Prize, £4 4*s.* and medal, Clinical Medicine; (*k*) Two Burney Yeo Entrance Scholarships, £80 each, open to students of Oxford and Cambridge on the nomination of the Regius Professors. The Warneford and Sambrooke Scholars are required to take the subjects of the Preliminary and Intermediate Examinations at King's College, and the Final Subjects at King's College Hospital.

Athletics.—The King's College Hospital Clubs and Societies Union was formed in 1908, and consists of the Listerian and Musical Societies, the Students' Common Rooms, and the various athletic and sports clubs. Admirable playing fields, over six acres in extent, have been provided for the use of the students on Dog Kennel Hill, Lordship-lane, S.E., about ten minutes' walk from the hospital. There are also Tennis Courts in the grounds of the Hospital and of " The Platanes," the hall of residence for students belonging to the hospital.

Fees.—The composition fee for Hospital work and Final subjects of the curriculum is 93 guineas if paid in one sum, or 95 guineas if paid in two instalments, in addition to the Entrance Fee of 10 guineas. The Calendar of the School will be sent on application to either of the following: Dr. H. Willoughby Lyle, *Dean*; Dr. S. C. Ranner, *Secretary of the Medical School*, King's College Hospital, Denmark Hill, S.E. 5.

LONDON HOSPITAL.—The hospital, with its Medical College and Dental School, is situated in the Mile End-road, E. The hospital contains 950 beds, which are in constant use, and is the only general hospital for East London. During last year 21,639 in-patients and 120,886 out-patients received treatment, while 7804 major operations were performed. 41,973 out-patients attended the special departments for diseases of the Eye, Ear, Nose, and Throat, Skin, Teeth, &c.,and the Obstetric, Orthopædic, Venereal, Radiological, Electro- and Physico-Therapeutical and Inoculation Departments. The hospital presents, therefore, a large field for clinical instruction, and in its Wards and Out-patient Departments exceptional opportunities are afforded for acquiring an extensive and practical experience in all phases of disease.

The Clinical Units in Medicine and Surgery coördinate the teaching of their subjects in the Hospital. The directors and their assistants give practical instruction in Elementary Clinical Medicine and Surgery to all students before they are allowed to enter the Wards and Out-Patient Department. Senior Students are encouraged to work with the units. Special courses of lectures and demonstrations are arranged in Medicine and Surgery and their ancillary subjects. Opportunities for research will be provided under the supervision of the staffs of the units.

Owing to the large number of patients more appointments are open to students before and after qualification than at any other hospital. Holders of resident appointments have free board. Special classes are held for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, for the Membership of the Royal College of Physicians, and for other higher examinations. Special entries for medical and surgical practice can be made. A residential Hostel on hospital grounds is provided for the convenience of students. The Clubs Union Athletic Ground of over 13 acres is within easy reach of the hospital.

Scholarships and Prizes.—At this school the successful candidates for the first items in the list here shown must enter for the course subsequent to passing

Teaching Staff.—The teaching staff of the University is organised under two heads: 1. Appointed teachers—i.e., such as are appointed by, and are paid out of the funds of, the University. 2. Recognised teachers—i.e., those who have been appointed and are paid by the several schools of the University and other institutions at which instruction is given under the auspices of the University, and who have been recognised by the Senate as conducting work of University standard. Courses by non-recognised teachers may also be approved in schools of the University. The lecturers in the Medical Sciences and the professors in the Faculties of Medicine in University College, London, and King's College, London, will be found enumerated under their respective schools.

Internal and External Students.—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who have matriculated at the University and who are pursuing a course of study approved by the University, either (*a*) under the direct control of the University or a committee appointed thereby; or (*b*) under one or more of the appointed or recognised teachers of the University. Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. Internal students must pursue their studies at one of the above centres, or at one of the medical schools connected with the University. These are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine and the Lister Institute of Preventive Medicine are also recognised as schools of the University in special departments. External students are all other matriculated students, and may pursue their studies at other universities and medical schools, presenting themselves for examination at the University.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), and the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*).

The curriculum for the Bachelor's degrees is now five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University, to be obtained from the Principal Officer, University of London, South Kensington, S.W 7, and the examinations formerly known as the Preliminary Scientific, the Intermediate, and the Final Examination in Medicine are now respectively entitled the First, Second, and Third Examinations for Medical Degrees. Part II. of the former Preliminary Scientific Examination has now been made Part I. of the Second Examination.

A. *Internal Students.*—In order to be admitted to the Bachelor's degrees a student must normally, after registration as an internal student, have: (1) *Attended* prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic and Applied Chemistry; Part II., Anatomy, Physiology, and Pharmacology, including Pharmacy and Materia Medica; (*c*) the Third Examination for Medical Degrees, or M.B., B.S. Examination; Medicine and Surgery, Midwifery and Diseases of Women, Pathology, Forensic Medicine and Hygiene.

B. *External Students.*—To be admitted to the Bachelor's degrees an external student must (1) have passed the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, and General Biology) will take place twice in each year, commencing on the Monday following Dec. 7th and on the first Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (Part I.): Organic and Applied Chemistry.—This examination will take place twice in each year, commencing on the Wednesday following the third Monday in March and on the afternoon of the Thursday following the second Monday in July. No candidate will be admitted to this examination within six months of having passed the First Examination.

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the fourth Monday in October and on the first Monday in May. No candidate will be admitted to this examination uless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises (1) Principles and Practice of Medicine; (2) Clinical Methods and Physical Diagnosis; (3) Clinical Medicine and Experience as Clinical Clerk; (4) Fevers; (5) Insanity (with clinical demonstrations at a recognised Asylum); (6) Therapeutics; (7) Vaccination; (8) Principles and Practice of Surgery; (9) Operative Surgery, Surgical Anatomy, Practical Surgery, and the Administration of Anæsthetics; (10) Clinical Surgery and Practice as Dresser; (11) Diseases of the Eye, Ear, Throat, and Skin; (12) Lectures and Demonstrations on Midwifery and Diseases of Women; (13) Practical Midwifery; (14) The Conduct of at least 20 Labours; (15) Experience as a Clinical Clerk in Gynæcological Work; (16) General Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; (17) Work in the Post-Mortem Room; (18) Forensic Medicine; (19) Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years and a course of instruction at a recognised Fever Hospital for two months. He must have had clinical instruction and must have held the posts of medical clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine (including Therapeutics and Mental Diseases). Pathology, Forensic Medicine and Hygiene, Surgery, Midwifery, and Diseases of Women. The subjects may be divided into two groups—namely: (1) Medicine, Pathology Forensic Medicine, and Hygiene; and (2) Surgery, Midwifery, and Diseases of Women. These groups may be taken either separately or together. The list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list. Bachelors of Medicine of this University who graduated in or before May, 1901, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates may present themselves for examiin the school buildings, and large athletic grounds at Wembley. A subscription to the Amalgamated Students' Club is payable by all General and Dental students. Full particulars on application to the Dean, Middlesex Hospital Medical School, W. 1.

ST. THOMAS'S HOSPITAL.—This Hospital received its present charter from King Edward VI., but as a monastic institution was in existence prior to the year 1207. The building occupies a unique position by the river, opposite the Houses of Parliament, and contains 630 beds. The in-patients last year numbered 8362, whilst the number of attendances as out-patients, including the casualty and light departments, was 379,329. There are special departments for the treatment of women, children, the eye, ear, nose and throat, skin, teeth, and for Orthopædics. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction. The Venereal Department has been established as part of the London County Council scheme. Departments for light treatment. X rays, and the Physico-therapeutic Department are also special features. A speech clinic has been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of general pathology, clinical pathology, chemical pathology, cardiology, and of treatment by serums and vaccines. Surgical operations take place in the main theatres every day except Saturdays at 2 P.M. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week. Clinical lectures are delivered every Wednesday during the sessions. All appointments in the hospital are open to students without extra fee. Clinical assistants to all the special departments are appointed every three months. A resident assistant physician and a resident assistant surgeon, at a salary of £200 each, are appointed biennially; also four hospital registrars (medical, surgical, obstetric, and ophthalmic), the two former receive a salary of £250 and the latter £50. Three assistants in the clinical laboratory are paid, one at the rate of £400, and two at £250 each, per annum. There is also an assistant in the laboratory for chemical pathology, paid at a salary of £200. Appointments open to students before qualification: Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third years' work. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity ward thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anæsthetics by one of the hospital anæsthetists. The Students' Club comprises a spacious restaurant and smoking and reading room. There is no occasion for students to leave the hospital buildings during working hours. The curriculum is arranged to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

Fees.—The annual fees are: for first year (preliminary subjects) £25, and for each subsequent year £50. These fees cover all tutorial classes, but do not include instruction in infectious fevers, pharmacy, and vaccination. Qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the medical secretary.

Scholarships and Prizes.—At this school there are five Entrance Scholarships—namely, two in Arts, equivalent to the tuition fees for the first medical examination; two in Natural Science, of the value of £150 and £60 respectively; and the University Scholarship of £100 in Anatomy, Physiology, and Chemistry. The value of all entrance scholarships must be taken out in tuition fees. The money value and subjects of examination of the remainder are as follows: (*a*) William Tite Scholarship for second-year students, £25; (*b*) and (*c*) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (*d*) Cheselden Medal, Surgery and Anatomy; (*e*) Mead Medal, Medicine, Pathology, and Hygiene; (*f*) Toller Prize, Medicine, Pathology, and Hygiene; (*g*) Bristowe Medal, Pathology, and Morbid Anatomy; (*h*) Solly Medal and Prize, biennially, Surgical Reports; (*i*) Cutton Memorial Medal in Clinical Surgery, biennial; (*j*) Wainwright Prize, Medicine, Pathology, and Hygiene; (*k*) Hadden Prize, Pathology; (*l*) Beaney Scholarship, £50 biennially, Surgery and Surgical Pathology; (*m*) Sutton Sams Prize, biennially, reports of cases in Obstetric Medicine; (*n*) Grainger Testimonial Prize, £31 10*s*. Anatomy and Physiology; (*o*) Louis Jenner Research Scholarship, tenable for two years, £60 annually, Pathology; and (*p*) Research Scholarship, tenable for two years, £200 per annum.

The Dean of the Medical School is Sir Cuthbert S. Wallace, and the Medical Secretary Dr. A. Elliot, from whom any further information may be obtained.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—University College has been constituted a University centre for the teaching of medical sciences. The College Faculty of Medical Sciences comprises the Departments of Physics, Chemistry, Botany, and Zoology (the Preliminary Medical Sciences); also the Departments of Anatomy, Physiology and Pharmacology (the Intermediate Medical Sciences), and the Department of Hygiene and Public Health (Post-Graduate Study).

Faculty of Medical Sciences.—Composition Fees.—For the courses required by the University of London. 1. For the First Medical Course, 35 guineas, entitling to one attendance and to the privileges of the Union Society for one session. 2. For the Second Medical (Intermediate) Course 80 guineas, payable in two instalments of 40 guineas each. This fee entitles to attendance at Anatomy and Physiology during three years and to one attendance at Organic and Applied Chemistry, Pharmacology, and Materia Medica, and to the privileges of the Union Society for two sessions.

For the medical education required by the Examining Board in England and the Society of Apothecaries. First examination, Parts I., II., III., 29 guineas, entitling to attendance for the First and Second Terms and to the privileges of the Union Society for one session; 35 guineas, entitling to attendance throughout the session and to the privileges of the Union Society for one session. First Examination, Part IV., and second examination, 80 guineas, payable in two instalments of 40 guineas each. This fee entitles to attendance during three years in all subjects but Practical Pharmacy and to the privileges of the Union Society for two sessions.

Scholarships and Prizes.—The first three items on the present list require a complete intermediate course at University College. The money value and subjects at examinations are as follows: (*a*) The Bucknill Scholarship, 135 guineas; (*b*) and (*c*) two Entrance Exhibitions, 55 guineas each, Chemistry, Physics, Botany, and Zoology; (*d*) Cluff Memorial Prize, £15 biennially, Anatomy, Physiology, and Chemistry; (*e*) Schäfer Prize in Physiology, £18 triennially; (*f*) Sharpey Physiological Scholarship, £105, Biological Sciences; (*g*) Morris Bursary for sons of deceased professional men, by nomination, tenable for two years, £16 a year; and (*h*) five Gold and five Silver Medals awarded annually in various departments.

Women students are admitted.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—Dean: Dr. G. F. Blacker. Vice-Dean: Dr. A. M. H. Gray. Secretary: G. E. Adams. Open to men and women students. Fees for Preliminary and Intermediate Course: See under University College. For the Final M.B., B.S. (London) Course, 112 guineas if paid in one sum, 115 guineas if paid in two instalments. as follows—first year, 70 guineas; second year, 45 guineas. This fee entitles to attendance on Lectures and Hospital Practice during three years and two Resident Obstetric Officers are appointed each year after competitive examination.

Primary and Intermediate Studies.—By an agreement with the University of London the School sends its Primary and Intermediate Students to receive their lectures and practical work at King's College, which is situated within four minutes' walk. This arrangement has proved successful.

Final Studies.—These are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations. Departments are also available for other final subjects of Materia Medica, Toxicology, and Operative Surgery.

An Institute of Pathology with a whole-time staff of scientific workers and fully equipped Laboratories has been established in the School. Students receive their training in Preventive Medicine, Pathology, and Bacteriology here, and are encouraged to undertake Research. Special facilities for Post-graduate Research and Study.

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital. Special lectures and demonstrations are arranged for Post-graduates.

The *Museum* contains over 4000 specimens, including a notable collection of over 800 gynæcological specimens, "The Cuthbert Lockyer Collection."

Students' Club.—The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, &c. The Club, which is under the control of a Committee of Students, provides needful athletic recreation, and includes the Medical Society.

Women Students.—Women students are accepted by the School and Hospital upon the same terms and conditions as men, and after qualification are eligible for resident Hospital appointments. A separate common-room and a female attendant are provided, but beyond this no further distinction is made. This system of co-education, under which men and women are placed on terms of complete equality throughout the whole of the curriculum, has been found to work successfully and to their mutual advantage.

Fees.—An entrance fee of 10 guineas and 8 guineas is payable by full-course and final-course students respectively, and an annual fee of 35 guineas covers all other expenditure, with the exception of 7 guineas for vaccination, dispensing, and fever hospital attendance, which must be taken outside the hospital. Membership of the Students' Club is included in these fees.

Further information may be obtained on application to the Dean, Dr. W. J. Fenton, Medical School, Charing Cross Hospital, London, W.C.

ST. GEORGE'S HOSPITAL.—This hospital has a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. One ward is set apart for Diseases Peculiar to Women. Children's beds are placed in all the women's wards. Two wards are allotted to ophthalmic cases.

Entrance Scholarships and Endowed Prizes of a total value of £600 are awarded annually; a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the University of London for students who enter during the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at either University College or King's College. Students then complete their course, without payment of any entrance fee, in a school entirely devoted to Clinical work.

Eight house physicians and eight house surgeons are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office:—Resident Assistant Physician and Resident Assistant Surgeon, at £350 per annum each; Medical Registrarship at £200 per annum; Surgical Registrarship at £200; Assistant Curatorship of the Museum at £100; Obstetric Assistantship (Resident) at £50; the post of Resident Anæsthetist at £100; the post (2) of Senior Anæsthetists at £50; the posts (2) of Junior Anæsthetists, each at £30. The St. George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises, and an athletic ground at Wimbledon. is an amalgamation of the Hunterian Society, the *Gazette*, and the chess, lawn tennis, boxing, hockey, rifle, and golf clubs. Students have the advantage of a library of medical and scientific books which is kept up to date.

Scholarships and Prizes.—At this school two entrance scholarships are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two University Entrance Scholarships, 90 guineas and £70 respectively. Anatomy and Physiology. The others are as follows: (*c*) William Brown Exhibition, tenable for two years and open to perpetual pupils having registrable qualifications, £135 per annum, Practice of Medicine, Midwifery, and Surgery; (*d*) William Brown Exhibition, tenable for three years and open to perpetual pupils qualified not more than three years previously, £49 per annum, Essay and Original Work; (*e*) Allingham Scholarship in Surgery for Students qualified not more than three years, £60, Competitive Essay; (*f*) and (*g*) two Brackenbury Prizes, one in Medicine and one in Surgery, £30 each, open to students of not more than five years' standing; (*h*) H. C. Johnson Memorial Prize, £15, Practical Anatomy; (*i*) Pollock Prize, £17, Physiology, Physiological Chemistry, and Histology; (*j*) Clarke Prize, £5; (*k*) Thompson Medal, £5, Clinical Reports; (*l*) Brodie Prize, £7, Clinical Reports; (*m*) Webb Prize, open to perpetual pupils, £30, Bacteriology; (*n*) Sir Francis Laking Memorial Prize £65, open to students having registrable qualifications.

Further information may be obtained from the Dean of the Medical School. Mr. R. R. James.

GUY'S HOSPITAL.—This hospital, founded by Thomas Guy in 1721 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 644 beds. The school buildings have been rebuilt and now offer very complete accommodation. Within the grounds of the hospital are situated the residential college, with accommodation for 60 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 20 minutes from the hospital.

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, ophthalmic house surgeons, clinical assistants, clerks to anæsthetists, surgeons' dressers, medical clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the Medical Council according to merit. The establishment of a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

A Post-graduate Course is held in connexion with the Fellowship of Medicine.

The following new Clinics have been opened: Salomon's Welfare Centre (for Maternity and Children) Tuberculosis Department, and V.D. Department.

Scholarships.—Seven entrance scholarships are awarded annually as follows:—(*a*) one War Memorial scholarship, providing a free Medical Education for five years—the annual value is about £10, to be awarded either in Arts or in Science, according to the discretion of the Examiners and to the percentage of the marks obtained; (*b*) one Arts scholarship of £100 for students under 21 years of age, Latin, English, Greek, or French or German, Arithmetic, Euclid, and Algebra; (*c*) one Science scholarship for students under 21 years, £120, Inorganic Chemistry, Physics, and Biology; (*d*) a Scholarship of £50, open to (*b*) Science Scholarships: Natural Science Scholarship, £60; Chemistry and Physics Scholarship, £30 and Two Scholarships in Anatomy and Physiology, £50 each. Summer Session: Two Scholarships in Anatomy and Physiology, £50 each. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Notes of Cases; Clinical Surgery Prize, £5, Notes of Cases; Chadwick Prize £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, 5 guineas, a Paper and Tests in Practical Work; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15; Jelf Medal awarded to Third-year Students; Second-year Scholarship, £20, Elementary Anatomy, Physiology, Histology, and Organic Chemistry; Daniell Scholarship, tenable for two years, £20, Chemistry; Rabbeth Scholarship, open to First-year Students, £20, Class Examinations in the Preliminary Scientific Course; and the Sambrooke King's College Scholarship in Science, value £25. The Dean is Dr. A. S. Woodwark, to whom inquiries may be addressed.

London (Royal Free Hospital) School of Medicine for Women, 8, Hunter-street, Brunswick-square, W.C.—The fee for the medical course for the degrees of the University of London and for the diplomas of the Royal Colleges of England and for other qualifications is £240 in five instalments. This sum includes library and laboratory fees.

The Royal Free Hospital contains 237 beds. Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital for Paralysed and Epileptic, and Brompton Chest Hospital.

An agreement has been made under which a certain number of students of the school may attend full clinical courses at St. Mary's Hospital, Paddington (305 beds).

Special courses are arranged for the Primary Fellowship Examination of the College of Surgeons; also for dental students in conjunction with the Royal London Dental Hospital, Leicester-square.

Students after qualification can hold the posts of house physician, house surgeon, obstetric assistants, clinical assistants, assistant anæsthetist, medical gynæcological, and surgical registrars, assistant pathologist, and museum curator; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics. Many other resident posts in London and elsewhere are also open to them.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments.

There are residential chambers at 8, Hunter-street, 25, Gordon-square, 16, Brunswick-square, 5, Mecklenburgh-square, and 36, Tavistock-square, and the Warden can be consulted on the subject of other residences for students. The Students' Union arranges the social, athletic, and other clubs and societies.

Scholarships and Prizes.—(*a*) Isabel Thorne Scholarship, £30. (*b*) St. Dunstan's Medical Exhibition, £60 a year, tenable for three or five years. (*c*) Mrs. George M. Smith Scholarship, £50 a year, tenable for three or five years and next to be awarded in 1921. (*d*) Bostock Scholarship, tenable for two or four years, and next to be awarded in June, 1923, £60. (*e*) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year. (*f*) Sir Owen Roberts Scholarship, £75 a year for four years. (*g*) Mabel Webb Research Scholarship, tenable for one year and renewable, £100, Physiology, Chemistry, or Pathology. (*h*) Fanny Butler Scholarship, tenable for four years; next award in July, 1922, £14 10*s.* (*i*) John Byron Bursary, tenable from two to four years, for students already in the School requiring assistance for the prosecution of their medical studies, application to the Secretary by March 31st; next award in March, 1922, £20. (*k*) Ellen Walker Bursary tenable for two years, awarded to a student beginning fourth year of medical study, £25 a year. (*l*) Helen Prideaux Scholarship, awarded every second year to a student who has become qualified during the two years immediately preceding the award, and to be spent in assisting the holder to further study, £40. (*m*) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £100, awarded annually in June. It is open to all medical women, preferably coming from India, or going to work in India, for assistance in Post-graduate study. (*n*) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year; next award in 1923. (*o*) Dr. Margaret Todd Scholarship, tenable for four years, £37 10*s.* a year, awarded in alternate years; next award in July, 1923. (*p*) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years, awarded every four years; next award in July, 1924. The Dorothy Chick Gift, £20, is awarded annually for efficiency in Practical Midwifery. Two Richardson-Kuhlmann Prizes are given each year, value £12, for proficiency in Clinical Obstetrics, value £8, for proficiency in senior subjects respectively. Two Evans Prizes of £2 2*s.* and £1 1*s.* are given each year on the results of the class examination in Midwifery. The Evans Prize for Operative Midwifery, value £5 5*s.*, is awarded yearly. The Edith Pechey Phipson Prize in Pharmacology, value £3 3*s.*, is awarded annually. There is also a small loan fund from which assistance can occasionally be given to students and to graduates who specially require pecuniary help. Prizes and Certificates of Honour are awarded in each class at the end of the session.

The Dean of the Medical School is Miss Aldrich-Blake, M.D., M.S.; the Honorary Secretary, Dr. May Thorne; and the Warden and Secretary, Miss L. M. Brooks, to whom inquiries may be addressed.

UNIVERSITY OF DURHAM.

Two Diplomas, one Licence, and seven degrees are conferred—viz., the Diploma in Public Health, Diploma in Psychiatry, the Licence in Dental Surgery, and the degrees of Bachelor of Medicine, Bachelor of Surgery, Doctor of Medicine, Master of Surgery, Doctor of Surgery, Bachelor of Hygiene, and Doctor of Hygiene.

For the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* there are four professional examinations. The subjects of the First Examination are—Elementary Anatomy, Elementary Biology, Chemistry, and Physics. The subjects of the Second Examination are—Anatomy and Physiology. The subjects for the Third Examination are—Materia Medica and Pharmacy, Pharmacology, Medical Jurisprudence, Public Health, and Pathology and Elementary Bacteriology. The subjects of the Fourth Examination are—Medicine, Clinical Medicine and Psychological Medicine, Surgery and Clinical Surgery, Operative Surgery, Midwifery and Gynæcology, Therapeutics, and Diseases of the Skin, of the Throat, Nose, and Ear, and of Children. It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age. He must also have obtained the degrees of Bachelor of Medicine and Surgery of the University of Durham and must have been engaged for at least two years subsequently to the date of admission to the first examination in Biology, Chemistry, and Physics. The value and the subjects of examination are as follows:—Price Scholarship £100, and one Entrance Scholarship of £50, subjects of First Medical Examination at the University of London; Epsom College Scholarship, free education, subjects of First Medical Examination as above; Price Scholarship, open to students of Oxford and Cambridge Universities, £52 10*s.*, Human Anatomy and Physiology; Buxton Scholarship, £31 10*s.*, subjects of Anatomy and Physiology; three Scholarships for Clinical Work, £20 each, Medicine, Surgery, and Obstetrics and Gynæcology; Sutton Prize, £20, Pathology; Duckworth Nelson Prize, biennial, £10, Practical Medicine, and Surgery; Letheby Prizes (2), £25, Chemistry and Chemical Pathology; eight Dressers' Prizes, amounting to £40, zeal, efficiency, and knowledge of Elementary Clinical and Minor Surgery; Hutchinson Prize, triennial, £40, Clinical Surgery; two Practical Anatomy Prizes, £6 and £4 respectively; Andrew Clark Prize, biennial, £26, Clinical Medicine and Pathology; James Anderson Prizes (4), £20, Elementary Clinical Medicine; Arnold Thompson Prize, £15, Medical and Surgical Diseases of Children; and Liddle Prize, triennial, £120.

Medical Research Funds.—Research Funds of over £26,000, including the Eliza Ann Alston Endowment Fund for Medical Research, provide valuable scholarships for men wishing to undertake research or desirous of preparing Theses for University degrees.

Dean: Professor William Wright, London Hospital Medical College, E.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—The Hospital and Medical School are situated close to Paddington station (G.W.R.) having on one side a poor district of 500,000 persons, and on the other side the residential district of Kensington and Bayswater. The hospital contains 305 beds and, by a scheme of affiliation, for teaching purposes, of the Paddington Infirmary, Paddington Green Children's Hospital, and Maida Vale Hospital for Nervous Diseases, the teaching facilities extend over 1000 beds. The Athletic ground (10 acres) is situated at Wembley and can be reached in 30 minutes by a constant service of trains.

Clinical Facilities.—Clinical Units in Medicine and Surgery were established in 1920, and have now been formally recognised by the University Grants Committee. St. Mary's being one of the six Medical Schools in London which enjoy this privilege. Lying-in beds have recently been added, and provide special facilities for the teaching of Practical Midwifery.

Institute of Pathology and Research.—Students specially interested in Pathology and Bacteriology have singular advantages at St. Mary's. The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F.R.S.

Appointments.—Three Research Scholarships of £200 each are awarded annually to students working in the departments of the institute; and preparation is being made to open 13 research beds. Clerkships in Pathology and Bacteriology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the Pathological and Bacteriological investigations of the wards, and learn the necessary technique under supervision. Sixty-four of these posts are available annually.

Complete Curriculum.—The Medical School provides complete courses of instruction, and students can join at once on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

Entrance Scholarships.—Five Scholarships (value £100, £52 10*s.*, £52 10*s.*, £50, £25), are awarded annually by competitive examination in September.

Fees.—Composition Fee for entire curriculum (5½ years) £200 in one sum, or £210 by five annual instalments. Composition Fee for Clinical curriculum (2½ years) 90 guineas in one sum, or 95 guineas by two annual instalments. As an alternative, students may pay an annual fee of 40 guineas with an entrance fee of 10 guineas.

MIDDLESEX HOSPITAL.—The hospital contains over 450 beds, with special wards for Cancer, Maternity and Gynæcological and Ophthalmological cases, and for Diseases of Children. Other special departments include those for Diseases of the Eye, Ear, Nose and Throat, and Skin; Nervous diseases, Orthopædic cases, Diseases of the Rectum and Venereal Diseases. There is also an Electro-Therapeutic department. The Cancer Charity, containing 92 beds and Special Investigation Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects. In the Electro-Therapeutic Department, students obtain instruction in the Treatment of Lupus and Cancer by the X ray method of treatment.

The Medical School, which now includes the Bland-Sutton Institute of Pathology and the Cancer Research Laboratories is fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, and for the Diplomas in Public Health, for which two courses are held yearly, commencing in April and October. Ample laboratory and class-room accommodation is provided. The teaching staff includes 5 Professors, 29 recognised Teachers, 8 Demonstrators, 4 tutors. The Bland-Sutton Institute of Pathology is completely equipped for routine hospital investigations, teaching and research work, and contains a new lecture theatre and large pathological, bacteriological, and clinical laboratories, also smaller laboratories for individual research work. A well-equipped Anatomical and Pathological Museum and Reference Library offer every facility for study.

Other features of interest are: the institution of a course in Medical Radiology and Electrology, under the direction of the "Joel" Professor of Physics. The D.P.H. course, under the direction of Dr. Charles Porter, M.O.H., St. Marylebone, will commence on Oct. 4th. Primary F.R.C.S. class will resume on Sept. 5th. Final F.R.C.S. class begins in Mid-September.

Special classes are held to prepare students for the Intermediate Examinations of the Universities.

Hospital Appointments.—All appointments are made without fee of any kind, and the following are appointed at intervals annually: six house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, one resident anæsthetist, and two resident officers to the special departments. The medical and surgical casualty officers are appointed twice a year. The medical, surgical, and obstetric and gynæcological registrars are appointed as vacancies arise. Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

Scholarships, Prizes, &c.—(*a*), (*b*), and (*c*). Three Entrance Scholarships, value £100, £50, and £25, and (*d*) a University Scholarship, value £50, are awarded annually in September. The successful candidates are required to become general students of the school. (*e*) A Freer Lucas Scholarship for Foundationers or Council Exhibitioners of Epsom College is awarded annually on the nomination of the Headmaster. There are also, (*f*) and (*g*), two Broderip Scholarships, value £60 and £10 respectively; (*h*) the Lyell Gold Medal and Scholarship, value £55 5*s.*; (*i*) the John Murray Medal and Scholarship, value £25 (awarded every third year); (*k*) the Freeman Scholarship, value £30; (*l*) the Hetley Clinical Prize, value £25; (*m*) the Leopold Hudson Prize, value 11 guineas; and (*n*) the Second Year's Exhibition, value 10 guineas. There are also numerous class prize examinations.

Fees.—The fees are arranged on a basis of an annual payment of approximately £42 for the five years of the curriculum. After five years, if the student is not qualified, the annual fee is £21.

The Amalgamated Students' Club includes the following: the Medical Society, the Common Room Society, Musical Society, the cricket club, the football clubs, the athletic club, the rowing club, the musical society, the chess club, the lawn tennis club, and the hockey club. There are a restaurant and gymnasium

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary to the Board, Joint Matriculation Board, 315, Oxford-road, Manchester. First Examination.—Chemistry and Physics and Elementary Biology. Second Examination.—Anatomy and Physiology. Third Examination.—General Pathology and Bacteriology, Materia Medica, and Practical Pharmacy. Fourth Examination (at the end of the fourth year).—Forensic Medicine, Toxicology, Public Health, Therapeutics, and Special Pathology. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery, Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital one month, and mental hospital three months. Vaccination instruction must be taken out and courses of Ophthalmology, Medical and Surgical Anatomy, and Operative Surgery.

Degrees of Doctor of Medicine and Master of Surgery.—At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both. Candidates have to present a thesis on some subject embraced in the medical curriculum, and pass a general examination in Principles and Practice of Medicine for the M.D., and one in Principles and Practice of Surgery, including operations on the cadaver, for the M.Ch. A thesis of exceptional merit may exempt from any part of these examinations.

Degree of Ph.D.—The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University. After the first year of the course candidates may carry on research elsewhere, under approved conditions, and on completing the course present an original thesis on the subject and to submit themselves for oral and possibly written examination.

Fees.—Matriculation, £2; First Examination, £2 10*s.*; Second Examination, £2 10*s.*; Third Examination, £2 10*s.*; Fourth Examination, £2 10*s.*; Final Examination, £10; M.D. or Ch.M., £12 10*s.*

At the University of Birmingham the following Scholarships are awarded:—(*a*) Myers Travelling Studentship of £150, tenable for one year, awarded by vote of committee to M.B., Ch.B. Birm., B.Sc. candidates, tenable at some University or Hospital not in Great Britain or Ireland; (*b*) Ingleby Scholarship of £10, awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (*c*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*d*) Sands Cox Scholarship of £42, tenable for three years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the July Matriculation; (*e*) Dental Scholarship of £37 10*s.*, Open Competitive Examination in subjects learned during apprenticeship: (*f*), (*g*), (*h*), and (*i*) Four Queen's Scholarships of £10 10*s.* each. In the Second and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and obtaining "first-class" marks. In the Third Examination the Scholarship is awarded to the student obtaining the highest "first-class" marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of Materia Medica and Practical Pharmacy. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination—that is, obtaining the greatest aggregate number of marks—provided that in each of the subjects of Medicine, Surgery, and Midwifery he gains not less than 60 per cent. of the total available marks; (*j*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*k*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases. The "Arthur Foxwell Memorial Medal" (Gold Medal) is awarded annually to the candidate passing the Final M.B., Ch.B., who obtains the highest marks in Clinical Medicine, provided the marks so gained be not less than 60 per cent.

Clinical Instruction.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital under the direction of the University Clinical Board. The hospitals possess more than 500 beds, treating annually over 8000 in-patients and 100,000 out-patients. The curriculum is adapted in the first place to the University of Birmingham, but it also meets the requirements of the examinations of other licensing bodies. At the General Hospital there are open to the students the following appointments: A surgical registrar, £200 per annum; a resident medical officer, elected annually (£155); a resident surgical officer, elected annually and eligible for re-election for three years (£180); a resident pathologist, elected for six months (£100); three house physicians and four house surgeons hold office for six months, receiving board, residence, and salaries at the rate of £100 a year; two house surgeons to the gynæcological, ophthalmic, and aural departments are elected every six months, receiving board, residence, and a salary of £100 a year; two assistant house surgeons are elected every three months, receiving board, residence, and salaries at the rate of £40 a year; a resident medical officer at the Jaffray Hospital, who is elected annually but is eligible for re-election, and who receives £150 a year; and a resident medical assistant at this hospital, who is not necessarily qualified, is provided with board and residence, and holds office for three months. At the Queen's Hospital there are open to the student the following appointments: Three house physicians, three house surgeons, and one obstetric and ophthalmic house surgeon, who hold office for six months and have salaries at the rate of £90 a year. Thirty-eight other appointments of varying value are at the City Workhouse and Workhouse Infirmary, at the Birmingham General and Branch Dispensaries, at the Birmingham Mental Hospitals, at the City Fever Hospitals, at the Children's Hospital, at the Birmingham and Midland Eye Hospital, at the Orthopædic and Spinal Hospital, at the Maternity Hospital, and at the Ear and Throat Hospital.

Post-graduate Courses.—A "Lectureship in Psychotherapy" was established in 1919 in the University, and courses of lectures are given annually by specialists in the subject. The "Ingleby Lectures" on some subject in connexion with "Diseases of Women and Children" are given annually by specially appointed lecturers. Other post-graduate courses are also arranged from time to time.

BIRMINGHAM GENERAL HOSPITAL.—374 beds are in daily use, 6930 in-patients per annum. Special wards for children, gynæcological, septic and infectious cases; special beds for eye, ear, and skin cases. About 50,000 out-patients per annum. Laboratories for bacteriology and morbid histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on the most modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held and to one attendance on Practical Pathology and Practical Surgery. Vaccination and attendance at a Fever Hospital are not included. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham, and for the medical education required by the Examining Board in England and the Society of Apothecaries. There are over 300 beds in the hospital.

Medical and Surgical Units.—Whole-time Directors of medical and surgical units have recently been appointed. They are responsible for the systematic teaching of the principles of medicine and surgery and are assisted by whole-time assistants. The teaching of practical medicine and surgery and of their special branches continues to be conducted by the honorary staff of the hospital.

The school has recently been the recipient of a large donation from the Rockefeller Foundation, which will enable it largely to increase its facilities for clinical and pathological study and also to establish an obstetrical unit on similar lines to those of medicine and surgery.

Special Departments, Clinical and Laboratory Facilities.—Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology, are admitted to work in the laboratories of the school by the Professor of Pathology, and under certain conditions can receive grants from the Charles Graham Medical Research Fund. A special course of instruction is given in conjunction with University College for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies. In the Dental School in Great Portland-street, formerly known as the National Dental Hospital, there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

Appointments tenable by Students.—Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Eight house physicians, eight house surgeons, four senior and four junior obstetric assistants (of the total number of resident officers not more than three may be held by women students at any one time) are selected annually by examination from among the senior students who have a medical qualification. The house physicians and house surgeons reside free in the hospital for six months, and the senior obstetric assistants for three months. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital: 1. The Resident Medical Officer. This officer is appointed for a period of two years and is chosen from amongst the more senior recent residents of the hospital. 2. The two Surgical Registrars are also chosen from among the more senior recent residents of the hospital. 3. The Obstetric Registrar. 4. Harker Smith Registrar. 5. Two Casualty Medical Officers and a Casualty Surgical Officer are appointed, each for a period of six months. 6. Assistant in Ear and Throat Department, appointed for one year. 7. Assistant in Ophthalmic Department, appointed for one year. 8. Registrar in Anæsthetic Department, appointed for one year. 9. Deputy Anæsthetists. During the absence of one or another of the Anæsthetists in the summer months a senior qualified student is appointed as a substitute and is granted a special certificate.

Museum of Pathological Anatomy.—The Museum is open for study from 9 A.M. to 5 P.M. Microscopic sections of most of the specimens in the Museum have been prepared and are available for the use of students on application to the Curator. The Museum contains 1100 admirable paintings by Sir Robert Carswell and Sir Charles Bell and a collection of old surgical instruments formerly belonging to Robert Liston.

The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee.

The Medical Library is open daily for the purposes of study to every student of the Medical School from 9 A.M. to 5 P.M., Saturdays 9 A.M. to 1 P.M. It contains about 13,500 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of Medical and Surgical Science, and (2) of promoting social intercourse among its members. All Students of the Medical School are eligible for membership. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine. In its social aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet court in the Medical School. The Athletic Ground, which is used in conjunction with the Union Society of the University of London University College, is situated near the G.W.R. station at Perivale.

Scholarships and Prizes.—At this School the first two Scholarships (*a*) and (*b*) entitle the holder to a complete course at University College and University College Hospital Medical School; the second two (*c*) and (*d*) entitle to a final course at the Medical School. The money value and subjects of examination are as follows:—(*a*) Entrance Scholarship, Bucknill, 135 guineas, Chemistry, Physics, Botany, and Zoology; (*b*) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (*c*) and (*d*) two Goldsmid Entrance Exhibitions, 112 guineas each, Anatomy and Physiology; (*e*) Graham Scholarship in Pathology, £400 per annum for two years, awarded by the Senate of the University of London; (*f*) Atkinson Morley Scholarship, tenable for three years, £45 per annum, Surgery; (*g*) Atchison Scholarship, tenable for two years, £55 per annum; General Proficiency in Medical Studies; (*h*) Magrath Clinical Scholarship, about £100, Clinical Cases; (*i*) Percival Alleyn Scholarship, about £60, Surgery; (*j*) Filliter Exhibition, £30, Pathology; (*k*) Erichsen Prize, £10 10s., Practical Surgery; (*l*) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (*m*) two Liston Gold Medals for Clinical Surgery; (*n*) Alexander Bruce Gold Medal for Pathology and Surgery; and (*o*) Tuke Silver and Bronze Medals for Pathology. (*p*) Radcliffe Crocker Travelling Scholarship for Dermatology. (*q*) Leslie Pearce Gould Travelling Scholarship for Surgery.

Residence of Students.—University College Hall, Ealing, is recognised by the Medical School authorities as a residential hostel. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge. Gentlemen who desire assistance in their studies should consult the Dean or Lecturers.

WESTMINSTER HOSPITAL.—The hospital contains 215 beds and affords relief to upwards of 1600 in-patients and 25,000 out-patients annually. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, for Orthopædic practice, for Diseases of Women, for Diseases of Children, for Radiography, and for the Light Treatment. The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school.

The usual registrarships and house appointments are open to male and female students.

By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster School for the teaching of these subjects at King's College. Students, however, may join the Westminster Medical School as formerly and may compete for Entrance Scholarships as heretofore.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: (*a*) Arts Scholarship, the "Guthrie," £80.

Public Health Department.—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

VICTORIA UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine is awarded by examination to registered medical practitioners.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University and one year at least having been passed in the University subsequently to the date of passing the first M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations. (These are now under revision.)

The First Examination.—(1) Inorganic Chemistry and Physics; (2) Biology; and (3) Elementary Organic Chemistry and Biochemistry. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into three parts: Part 1, Inorganic Chemistry and Physics; Part 2. Biology; Part 3, Elementary Organic Chemistry and Biochemistry. The candidates may pass in these parts separately under certain conditions.

The Second Examination. — (1) Anatomy and Histology; (2) Physiology, including Physiological Chemistry. Candidates may pass in (1) and (2) separately under certain conditions.

The Third Examination.—(1) Pathology; (2) Pharmacology and Therapeutics. These subjects may be taken separately under certain conditions.

The Final Examination.—(1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynæcology (including Clinical and Practical); (4) Forensic Medicine (including an Oral Examination); (5) Hygiene and Preventive Medicine. The Final Examination is divided into two parts.

Candidates for the Second Part of the Final Examination must have completed the fifth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be written and practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The degree is conferred in the following branches: Surgery (Branch I.), Gynæcology (Branch II.), Ophthalmology (Branch III.), Laryngology, Otology, and Rhinology (Branch IV.).

Scholarships, Fellowships, and Prizes.—At this University there are 22 Foundation Scholarships, 12 Exhibitions, five being for subjects connected with medical study, a Surgical Prize, a University Fellowship (Leech Fellowship, £100), Research Fellowships in Public Health, and Honorary Research Fellowships. 13 Entrance Scholarships are tenable for Medical courses; one Scholarship is offered in Surgery, Biology, Physiology, and Diseases of Children respectively, and one General Medical and Surgical. Exhibitions are offered in Physiology and Anatomy, and one for French and German. "The Dumville" Surgical Prize is awarded on the results of the Final Examination in Surgery in the Summer Term, £15. The Leech Fellowship (£100) is for the encouragement of study and research, and is open to persons who have graduated M.B., Ch.B., in the University not more than 18 months previously. The Honorary Research Fellowships, tenable for two years, conferring the right of free use of the laboratories, are awarded generally in October on application, with evidence of capacity for independent investigation.

There are many entrance scholarships, the examinations for which are held in the month of May. Full particulars can be obtained from the Registrar.

The Medical School.—This medical school, largely extended in 1920, is provided with dissecting-rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped for cancer research and investigation in general pathology. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica. In the public health department, which is lodged in a separate institute in York Place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, a lunatic asylum, and a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary, which together with the associated hospitals at Cheadle contains 1109 beds, exclusive of those reserved for military cases, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

Clinical Instruction.—THE MANCHESTER ROYAL INFIRMARY.—The Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 628 patients. The medical side consists of five units, each unit having a testing room for the scientific investigation of morbid products and a class-room. The surgical beds are also arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing, and apparatus rooms, and its own class-room attached. All of these units are occupied. The fine educational block provides very handsomely for the wants and comforts of the students, there being separate suites of rooms for the men and the women, and also a large common reading room, a lecture theatre, and a museum. The present annual average number of in-patients is 13,650, of out-patients 27,000, and the list of casualties in the accident room has averaged 17,000 per annum. About 9000 operations are performed annually in the operation theatres. Associated with the infirmary are: (1) the Convalescent Hospital at Cheadle, containing 136 beds;

these degrees in research work, or in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The candidate for the M.D. degree may present an essay or undergo a special examination in the Theory and Practice of Medicine. The subjects of examination for the M.S. are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Medicine (without residence).—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under 40 years of age and shall have been in active practice for 15 years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession. The fee will be 50 guineas, of which 20 guineas will be retained if the candidate fails to satisfy the examiners.

Candidates for any of the above degrees, diplomas or licence, must give at least 28 days' notice to Professor Howden, Registrar, College of Medicine, Newcastle-upon-Tyne. In the case of the M.D. (essay) examination candidates must send in their essays before the 1st of April.

Scholarships and Prizes.—In connexion with this University the following Scholarships and prizes are awarded:—(*a*), (*b*), (*c*), and (*d*). Four Scholarships of £25 a year each, tenable for four years; the examination will be the September Matriculation Examination. Candidates must take English, Latin, Arithmetic, Euclid, Algebra, Geography, English History, and one, or two, of the three languages—French, Greek, German. (See College Calendar for special books.) Open to candidates desirous of being admitted as Medical Students. The successful candidates must take out their entire curriculum at the University of Durham College of Medicine, Newcastle-upon-Tyne. (*e*) Pears Scholarship of £50 a year (when vacant), tenable for three years; Matriculation Examination.—At the College of Medicine are: (*f*) Dickinson Scholarship, interest on £400 and gold medal; examination in Medicine, Surgery, Midwifery, and Pathology. Open to full students of the College of Medicine who have passed the third M.B. Examination. (*g*) Tulloch Scholarship, interest on £400; examination in Elementary Anatomy, Biology, Chemistry, and Physics. (*h*) Charlton Memorial Scholarship, interest on £700; examination in Medicine. Open to full students of the College entered for the class on the Principles and Practice of Medicine. (*i*) Gibb Scholarship, interest on £500; awarded annually as a Scholarship in Pathology to full student who passes the best examination in that subject. No student is eligible after completion of his curriculum. (*j*) Luke Armstrong Memorial Scholarship, interest on £680: Original Essay in Comparative Pathology. Open to all Graduates in Medicine or Hygiene and candidates for these degrees who have spent six months at the University and whose age does not exceed 30 years. (*k*) Stephen Scott Scholarship, interest on £1000; Original Essay on any Surgical subject. Open to any graduate in Medicine or Surgery of the University or any student of the College of Medicine. Student's age must not exceed 30 years. (*l*) Heath Scholarship in Surgery, of the value of £200, awarded every second year. All Graduates in Medicine or Surgery of the University are eligible. (*m*) Philipson Scholarships (2). The interest on £1800 to the candidates who obtain the highest marks in the Final M.B., B.S. Examinations held in March and June respectively. (*n*) Gibson Prize, interest on £250 stock; examination in subject of Midwifery and Diseases of Women and Children. Open to students who have attended one course of lectures on Midwifery and Gynæcology. (*o*) Outterson-Wood Prize, interest on £250, in Psychological Medicine. (*p*) Turnbull Prize and Medal; examination in Surface Anatomy. Open to students at end of their second winter session.—At the Royal Infirmary is (*q*) Goyder Memorial Scholarship, interest on £325; awarded annually to student who most distinguishes himself in Clinical Medicine and Clinical Surgery at the Royal Infirmary. For further information apply to Professor R. Howden, Registrar of the College.

THE COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—Clinical instruction is given at the Royal Victoria Infirmary, containing about 600 beds. In it adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work. Post-graduate classes are held.

NEWCASTLE-UPON-TYNE ROYAL VICTORIA INFIRMARY.—The Infirmary was founded in 1751, but has been entirely rebuilt, the new hospital being opened by His late Majesty King Edward VII. in 1906. The number of beds is 550. The number of in-patients annually is 10,000 and of out-patients 84,000. The medical students of the University of Durham attend the practice of this hospital. Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are held by the Assistant Physicians, Assistant Surgeons, and Surgical Registrars weekly, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic, Throat, Nose, and Ear, Skin, Gynæcological, and Electrical. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory, in which all clinical bacteriological investigations are carried out—opsonic indices estimated with a view to treatment by vaccines and serums, &c. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The surgical practice is especially good. The session opens on April 17th and Oct. 2nd of each year. Applications for detailed information should be made to the Dean, Dr. Horsley Drummond, at the hospital.

There are other institutions in addition to the Royal Victoria Infirmary at which the student of medicine of the University of Durham can receive clinical instruction. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological Medicine at the Sunderland Mental Hospital, Ryhope. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health. Ophthalmology is further taught at the Northumberland, Durham, and Newcastle Infirmary for Diseases of the Eye. Secretary: Mr. Richard Smith, 61, Westgate-road, Newcastle-on-Tyne.

Post-Graduate Courses.—General and Special Post-Graduate courses are held under the joint auspices of the Council and the College of Medicine, the honorary staff of the Royal Victoria Infirmary, and the British Medical Association.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and Ph.D. (for Research Study), and also a degree and a diploma in Public Health. The course for the Bachelors' degrees extends over five years from the date of commencement of professional study. As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Chemistry, Physics, and Elementary Biology. In the case of such students at least three years must be spent in attendance upon classes at the University. The fifth year may be spent at any other medical school recognised by the University.

all subjects at the same examination. Candidates must have completed the fifth year of professional study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates must have taken the M.B, Ch.B. at least one year previously, and must since have held for not less than six months a surgical appointment in a public hospital.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy Surgical Pathology, and Bacteriology.

Scholarships, &c.—At this University, in addition to four Edgar Allen scholarships of £125 a year for three years, holders of which can take the courses in the Faculty of Medicine, there are 8 scholarships and a Town Trust Fellowship. Full particulars as to curriculum, scholarships, &c., may be had on application to the Registrar or to the Dean of the Medical Faculty.

The Medical School.—The new buildings of the University opened in 1905 are situated at the west end of the city, adjoining Weston Park, and the Medical Department occupies the entire north wing of the University quadrangle. The various athletic and other students' societies are under the management of a Students' Representative Council, elected annually. There are large and comfortable common rooms both for men and women students. A refectory is open daily at the University where students may obtain refreshments, lunch, dinner, &c., at extremely moderate prices. The University journal, *Floreamus*, edited by a committee of staff and students, is published each term. The University Halls, "Oakholme," Clarkehouse-road, and "Tapton Cliffe," Fulwood-road, are recognised by the Senate as halls of residence for women students; full particulars may be obtained of the tutor for women students.

Clinical Instruction.—The University is within easy reach of the various hospitals with which it is connected for clinical purposes. These are as follows: The ROYAL INFIRMARY (Secretary, Mr. J. W. Barnes), containing 326 beds, with an annual average number of over 3800 in-patients, over 11,500 out-patients, and over 23,000 casualties; the Royal Hospital (Hon. Sec., *pro tem.*, to the medical and surgical staff, Mr. Vincent Townrow), with 191 beds, and an annual number of 3000 in-patients, over 20,000 out-patients, and nearly 20,000 casualties; and the Jessop Hospital for Diseases of Women, with 80 beds, about 900 in-patients, and about 3057 out-patients; also a Maternity department, with about 450 in-patients per annum and about 700 out-patient cases attended. Special courses on Fevers are held at the City Fever Hospitals (600 beds) and on Mental Diseases at the South Yorkshire Asylum (1610 beds.) For purposes of clinical practice the practices of the Royal Infirmary and Royal Hospital are amalgamated, giving a total of 511 beds for the treatment of medical, surgical, and special cases. There are special departments for the treatment of Diseases of the Eye at each institution, with wards assigned to them. In addition to these the Royal Infirmary has special departments for the treatment of Diseases of the Skin and Ear, with beds assigned to them, whilst at the Royal Hospital there are special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases. Instruction is also given at the South Yorkshire Asylum (1694 beds). During the last year over 6000 patients passed through the wards of the two institutions, while those attending as out-patients numbered over 45,000. The department of Pathology and Bacteriology in the University is fitted with every requirement for the most advanced work in these subjects.

Fees.—The Composition Fee is £36 a year for each of the five years.

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike.

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five and a half years, of which three shall have been passed in the University, and two of these three subsequent to pass in the second examination. All candidates for the degrees of M.B., Ch.B., are required to satisfy the examiners in the several subjects of three examinations.

The First Examination.—The subjects of examination are: Chemistry (Inorganic), Physics, and Biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.)

The Second Examination.—The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I.) and Advanced Anatomy and Physiology (Part II.). Parts I. and II. may be passed separately or together.

The Final Examination.—The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine, Toxicology, and Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II.). Candidates may pass I. and II. together, or separately, and Forensic Medicine and Toxicology may, at the option of the candidate, be taken either with Part I. or Part II.

Degree of Doctor of Medicine.—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—Candidates shall be Bachelors of not less than two years as such, during which period they shall have attended the Surgical Practice of an institution approved for the purpose. They shall pass an examination in Surgical Anatomy, Pathology, and Bacteriology, and Operative, Clinical, and General Surgery, and present to the University a Dissertation on some subject of Surgery.

Clinical Instruction.—The allied hospitals (BRISTOL ROYAL INFIRMARY and BRISTOL GENERAL HOSPITAL) have between them about 600 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye, Throat, and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and for senior and junior students. Clinical instruction in all the special departments. The Jaffray Branch Hospital contains 56 beds.

QUEEN'S HOSPITAL (Beds 223).—Similar arrangements for clinical teaching are made here, and the material also is excellent. Ward and tutorial classes and post-graduate courses are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons. There are also special departments for gynæcology and ophthalmology, radiography, bacteriology, massage, electricity, whirlpool baths, electro-cardiograph, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham.—This hospital possesses 120 beds, and there is an average daily attendance of out-patients of 250. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations. Post-graduate courses are available on various subjects when a sufficient number of graduates are present. A limited number of Non-Resident Clinical Assistants posts are available to qualified practitioners, particulars of which can be had on application to the General Superintendent.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Master of Hygiene (M.H.), and Master of Orthopædic Surgery (M.Ch.Orth.).

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 21 years on the day of graduation. At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The fee is £5 for each examination. The subjects of the First Examination are: (1) Chemistry, Inorganic, Organic, and Physical; (2) Biology (Zoology and Botany); and (3) Physics. The examination is divided into two parts—namely, (1) Chemistry and Physics, and (2) Biology; and candidates may present themselves in these parts separately. The subjects of the Second Examination are (*a*) Anatomy and Physiology (including Physiological Chemistry and Histology), and (*b*) Materia Medica and Pharmacy and Pharmacology. Candidates may present themselves in (*a*) or (*b*) separately. The subjects for the Final Examination are: (1) General Pathology, Morbid Anatomy, and Bacteriology; (2) Forensic Medicine, Toxicology, and Public Health; (3) Obstetrics and Diseases of Women; (4) Surgery, Systematic, Clinical, Operative, and Practical, including Ophthalmology; (5) Medicine, Systematic and Clinical, including Mental Diseases and Diseases of Children, and Therapeutics. The Final Examination is divided into three parts, the first consisting of subject (1), the second of subject (2), the third of subjects (3), (4), and (5). Candidates may present themselves in these parts separately. Candidates for the third part must have completed the fifth year of medical study.

Degrees of Doctor of Medicine and Master of Surgery.—No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least one year has elapsed since he passed the examinations for those degrees, or, in the case of the degree of Doctor, unless, having obtained substantially equivalent degrees in an approved University, he has subsequently spent two years in the University or in the Clinical School in the performance of research or the conduct of systematic clinical observations. Candidates for the degree of Doctor of Medicine are required to present a dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine: provided always that original work published in scientific journals or separately shall be admissible in lieu of, or in addition to, a dissertation specially written for the degree. Graduates of the University who are candidates for the degree of Doctor of Medicine may be admitted by examination alone.

The University has recently established a Diploma in Medical Radiology and Electrology—Part I., Physics; Part II., Radiology and Electrology. The parts may be taken at one examination or separately.

At this University the following Scholarships and Fellowships and Prizes are awarded:—(*a*) and (*b*) Robert Gee Entrance Scholarships, two annually, of £25 each, tenable for two years, Joint Matriculation Board Examination held in July, open to First M.B. Course Students; (*c*) Lyon Jones Scholarship, No. 1, of £21 per annum, tenable for two years, Competitive Examination among Junior Students in First M.B. Subjects, Perpetual Course at the University; (*d*) Lyon Jones Scholarship, No. 2, of £21, Competitive Examination among Senior Students in Anatomy, Physiology, Pharmacology, and Materia Medica; (*e*) Derby Exhibition of £15, Competitive Examination among Fourth- or Fifth-year Students in Clinical Subjects, and Clinical School Exhibition of £15 annually for Fourth- or Fifth-year students; (*f*) University Scholarship of £25 for one year, awarded on results of Second Examination for the degrees; (*g*) Holt Fellowships, Physiology and Pathology, of £100 each, for one year; (*h*) Gee Fellowship, Anatomy, of £100, for one year; (*i*) John Rankin Fellowships in Anatomy, two, each of the value of £120, tenable for two years; (*j*) Johnston Colonial Fellowship, Bio-Chemistry, of £100, for one year; (*k*) John W. Garrett International Fellowship, Bacteriology, of £100, for one year; (*l*) Thelwall Thomas Fellowship, Surgical Pathology, of £150, for one year; (*m*) Ethel Boyce Fellowship in Gynæcological Pathology, of £100, for one year; (*n*) Mary Birrell Davies Memorial Fund Scholarship, of the value of £60, tenable for four years, offered for competition in alternate years; open only to women students who will have attained the age of 19 on the first day of October next following the award; (*o*) Rankin Exhibition in Practical Anatomy, of £25, for one year; numerous prizes and medals.

Medical School Buildings.—Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation. All the laboratories and class-rooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Experimental Medicine and Biochemistry; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology. A new building for Tropical Medicine has recently been opened.

Clinical Instruction.—The Clinical School of the University consists of four general hospitals—the ROYAL INFIRMARY, the DAVID LEWIS NORTHERN HOSPITAL, the ROYAL SOUTHERN HOSPITAL, and the STANLEY HOSPITAL; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women, the Royal Liverpool Children's Hospital, St. Paul's Eye Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of about 1134 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school.

£3 3*s.*: re-examination in Physics, £2 2*s.*; re-examination in Biology, £3 3*s.* Second Conjoint: This examination is in two parts—viz.: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacology. A candidate must have attended at a recognised medical school, lectures on Anatomy, Physiology, and a course of Practical Physiology and Histology, and have dissected for twelve months during the ordinary sessions. He must also attend three months' lectures or demonstrations in Pharmacology and receive instruction in Practical Pharmacy. Part II. may be passed at the same time as Part I., or before or after that part, provided the conditions of admission to the whole examination have been fulfilled. The study of Anatomy and Physiology before passing in two of the three subjects of the first examination is not recognised. If rejected, a candidate before being admitted to re-examination must continue his studies at a recognised medical school for not less than three months.

Second Examination: £10 10*s.*; re-examination in Part I., £6 6*s.*; re-examination in Part II., £3 3*s.*

The subjects of the *Third* or *Final Examination* are: Part I., Medicine, including Medical Anatomy, Pathology, Therapeutics, Forensic Medicine, and Public Health. Part II., Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances. Part III., Midwifery and Diseases Peculiar to Women. Candidates may present themselves for Parts I., II., and III. of the examination separately or together at the expiration of not less than two years (24 months) from the date of passing the Second Examination on production of the certificates of study required for the respective parts, provided that the examination is not completed before the expiration of five years from the date of passing the Preliminary Examination.

The fees for admission to the *Third* or *Final Examination* are as follows: Third Examination: £21; re-examination in Part I., Medicine, £6 6*s.*; Part II., Surgery, £6 6*s.*; Part III., Midwifery and Diseases of Women, £4 4*s.* Members of English, Scotch, or Irish Universities £5 5*s.* for first admission to the examination and £36 15*s.* for the diplomas.

A candidate referred on the *Third* or *Final Examination* will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First and Second Examinations of the Examining Board, may enter for the Final Examination at the expiration of two years from the date of passing in Anatomy and Physiology on production of the required certificates.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First and Second Examinations of the Examining Board may present themselves for the Final Examination under special conditions. The Board also grants Diplomas in Psychological Medicine, in Ophthalmic Medicine and Surgery and in Tropical Medicine and Hygiene. Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, a Colonial, or a Foreign University. Particulars and conditions of admission to all examinations, fees, &c., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, London, W.C.

ROYAL COLLEGE OF PHYSICIANS OF LONDON:
THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—Every candidate must have attained the age of 25 years, and be already registered or have passed a qualifying examination in accordance with the Medical Act of 1886, or obtained the degree of Doctor or Bachelor of Medicine at a University in the United Kingdom, in India, or a British colony, or foreign qualification, for which the courses of study and the examinations have been adjudged by the Censors' Board to be satisfactory. The nature and extent of this examination will, in the case of each candidate, be determined by the Censors' Board. All other candidates must produce proof of having passed the examinations required for the Licence of the College. The examination is directed partly to pathology and partly to the practice of medicine and may be modified in circumstances to be ascertained by application to the Registrar. The fee for admission as a Member of the College is 40 guineas, except when the candidate for Membership is a Licentiate of the College, in which case the fee already paid for the Licence shall be deducted from the 40 guineas. The fee for the examination is £6 6*s.*

Fellowship.—The *Fellows* are selected annually from the ranks of the *Members* by the Comitia of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND:
THE FELLOWSHIP.

The Royal College of Surgeons of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology, and those of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examinations are partly written and partly vivâ voce and include the examination of patients and the performance of operations on the dead body. The First Examination will in future years be held in June and December and the Second Examination in May and November.

The fees for examination are:—First Examination, first admission 8 guineas, and for each re-admission 5 guineas. Second Examination, each admission, 12 guineas. Of such examination fees 20 guineas will be reckoned as part of the fee payable upon admission to the Fellowship. The fee to be paid upon admission to the Fellowship is 30 guineas, except when the candidate is a Member of the College, in which case the fee is 20 guineas.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a Member is admissible after passing the First and Second Examinations of the English Conjoint Board, of the equivalent examinations in his University, on the production of certificates of attendance upon certain prescribed courses.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination, on producing satisfactory evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees of universities recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised

(2) the Royal Lunatic Hospital at Cheadle, accommodating with its branches 430 patients; and (3) the Central Branch in the city for casualty and out-patient work, and 50 beds for pensioners. The Associated Hospitals thus contain 1244 beds and are under the same management. Women students are admitted on the same terms as men.

Fees.—Medical Practice: Three months, 7½ guineas; six months, 12 guineas; 12 months, 18 guineas; full period required by the Examining Boards, 60 guineas.

Two Entrance Scholarships in Medicine of the value of £100 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are mentioned in the College Syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

The Dean of Clinical Instruction is Dr. T. H. Oliver.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, Gartside-street, Manchester, and St. Anne's-on-the-Sea.—The hospital contains 190 beds and 28 in the Convalescent Home, St. Anne's-on-the-Sea. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. A new Massage and Electro-therapeutic Department is to be opened shortly. Out-patients are seen daily at 9 A.M. at the new Out-patient Department, Gartside-street, Manchester, Secretary: Mr. W. M. Humphry.

THE MANCESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road, Manchester.—The hospital contains 70 beds. Out-patients are seen daily from 8.30 to 10 A.M.

UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University, one of which must be subsequent to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination.

The First Examination.—The First Examination consists of: Part I., Physics and Chemistry; Part II., Zoology and Botany. Candidates will be allowed to pass the two parts separately.

The Second Examination.—The Second Examination consists of: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacy. Candidates will be allowed to pass the two parts separately.

The Final Examination.—The Final Examination consists of: Part I., Pathology and Bacteriology. Part II., Forensic Medicine and Public Health. Part III., Medicine: Systematic and Clinical, including Mental Disease and Diseases of Children; Surgery—Systematic, Clinical, and Practical; Obstetrics, and Gynæcology—Systematic, Clinical, and Practical; Pharmacology and Therapeutics. Candidates will be allowed to pass Parts II. and III. separately or together, and they may present themselves for examination in Part I. at the end of the tenth term.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery of the University (or of Victoria prior to December, 1904) and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation and, if the dissertation be accepted, may be required to pass an examination.

The first term commences on Oct. 3rd. Prospectus, &c., can be obtained from the Dean of the Medical School.

Post-graduate work.—Practitioners wishing to attend Infirmary practice during short periods may do so on terms which may be obtained from the Clinical Sub-Dean.

Clinical Instruction.—THE LEEDS GENERAL INFIRMARY, in connexion with this medical faculty, has accommodation for 620 in-patients, including 88 beds at branch hospitals in the country. During the last year 9495 in-patients and 37,746 new out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electro-therapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are in operation. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate must have attained the age of 21 years on the day of graduation and pursue the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

The First Examination.—The subjects of the examination are Chemistry, Physics, and Biology. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each.

The Second Examination.—The subjects of the examination are Anatomy and Physiology.

The Third Examination.—The subjects of the examination are Pathology, Pharmacology, Applied Anatomy and Applied Physiology for students who start work for the degree now. A candidate entering for the first, second, or third examination, who shall obtain a certain minimum of marks in one subject of either examination and pass creditably in the other subjects, may enter for such one subject separately in a subsequent examination. Candidates must have completed the fourth winter session of professional study.

The Final Examination.—The subjects of the examination are Medicine (including Forensic Medicine, Public Health, Mental Diseases, and Disease of Children); Surgery; and Obstetrics (including Gynæcology). Candidates must satisfy the examiners in diseases of the eye, ear, throat, and nose, skin diseases, plastic surgery, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction, ordinarily including laboratory classes, and lectures are given in the wards and out-patient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are four Resident Medical Officers, and Clinical Assistants are appointed under certain conditions. A special post-graduate course will be held from Sept. 26th to Oct. 8th. Further particulars in regard to the hospital may be obtained from Mr. H. W. Carson, Secretary to the Medical Committee, 111, Harley-street, W.; or from Dr. A. J. Whiting, Dean of North-East London Post-Graduate College, 19A, Cavendish-sq., W. Secretary: Mr. F. W. Drewett.

London Temperance Hospital, Hampstead-road, N.W. (Established 1873; Incorporated 1917).—The hospital contains 120 beds. The in-patients in 1920 were 1339, and the out-patients and casualties numbered 16,731 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Operations: Mondays at 2 P.M., Tuesdays, Wednesdays, Thursdays, and Fridays at 9 A.M.

Hampstead General and North-West London Hospital.—The Hampstead General Hospital (Haverstock-hill) and the North-West London Hospital (formerly at Kentish Town) have been amalgamated since 1907. The Hampstead General Hospital (128 beds—viz., 102 free, 6 isolation, &c., and 20 paying or contributory) accommodates the in-patients from the districts hitherto served by both hospitals. The out-patients, with the exception of Hampstead casualty and emergency cases, attend exclusively at the Out-patients department, Bayham-street, Camden Town. Further particulars from the Secretary at the hospital.

Elizabeth Garrett Anderson Hospital, 144, Euston-road, N.W.—A number of the students of the London School of Medicine for Women work in the E.G.A. Hospital under the visiting staff, and in return for much valued clinical gynæcological teaching they perform the duties assigned to students in the wards of a general hospital. Post-graduate courses in the treatment of venereal disease are held in conjunction with the London School of Medicine for Women. Secretary: Miss Imogen H. Murphy.

South London Hospital for Women, South Side, Clapham Common, S.W.; Out-patient Department: 86-90, Newington Causeway, S.E.—This hospital, officered entirely by medical women, is a general hospital for women, girls, and small children of both sexes, and provides accommodation for 80 patients. All diseases are treated with the exception of acute infectious fevers and mental disease. There are Ophthalmic, X ray, Pathological and Dental Departments. The hospital is a centre for the treatment of venereal diseases under the Public Health (Venereal Diseases) Regulations, 1916. The provision of additional facilities for post-graduate training for medical women is one of the special objects of the hospital. The number of in-patients treated during the year 1919 was 1190. At the Out-patient Department in Newington Causeway 7071 new cases were treated during the past year, the total number of out-patient attendances amounting to 31,485. Clinical assistants (qualified women only) are from time to time appointed in the Out-patient Department. Two resident students act as clinical clerks in the surgical wards. Secretary: Miss M. E. Ridler.

French Hospital and Dispensary, Shaftesbury-avenue, W.C.—This hospital, which was founded in 1867 to afford medical treatment for poor foreigners who speak the French language, has 74 beds. The Convalescent Home and Retreat for Aged French People at Brighton contains 61 beds. Secretary: Mr. G. Pondepeyre.

Italian Hospital, Queen-square, W.C.—This institution was established in 1884 for the maintenance and medical treatment of Italian and Italian-speaking people, irrespective of their religious and political opinions, who may be suffering from sickness or bodily infirmity, but the sick poor of any nationality are also admitted for treatment. The institution also provides surgical and medical relief to Italians and others not being inmates of the hospital. It has 50 beds.

German Hospital, Dalston, E. 8.—This hospital was founded in 1845 with the object of supplying medical aid to poor people speaking the German language and for others in cases of emergency and accident. It has 124 beds and a sanatorium with 10 beds.

National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square, Bloomsbury, W.C.—The hospital, with the Finchley branch, and branches in Bloomsbury and Clapham Park, contains 270 beds and cots. The physicians attend every Monday, Tuesday, Thursday, and Friday at 2 P.M. In- and out-patient practice at that hour. Clinical Clerks are appointed under the in-patient and out-patient physicians. Post-graduate Courses of Lectures and Demonstrations are held three times every year, usually commencing in January, May and October and lasting eight weeks. The hospital has been recognised by the Conjoint Board for England as a place where part of the fifth year may be devoted to clinical work. All communications concerning clinical appointments, lectures, hospital practice, and fees should be addressed to the Secretary at the hospital.

Hospital for Epilepsy and Paralysis, &c., Maida Vale, W. (85 beds).—Both in-patient and out-patient departments of this hospital are open free to students as well as to medical graduates. Secretary and General Superintendent: Mr. H. W. Burleigh. The out-patient department is open every week-day except Saturday at 2 P.M.

West End Hospital for Nervous Diseases.—Out-patient Department, 73, Welbeck-street, W. 1; In-patient Department, St. Katherine's Lodge, Gloucester Gate, Regent's Park, N.W. Graduates in medicine and senior students may attend demonstrations in the Wards and Out-patient Departments. The examination for the Savill Prize, open for competition among those who have attended twenty-five clinics during the year, will be held in July, 1922.

Bethlem Royal Hospital, St. George's-road, S.E.—This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They are permitted to reside in the hospital for a term generally not exceeding six months, commencing May 1st and Nov. 1st, and are provided with apartments, complete board, attendance, laundry, and a salary at the rate of £100 per annum. They are under the direction of the Physician Superintendent and are elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive Clinical Instruction in the wards of the hospital and qualified practitioners and other students may attend for a period of three months on payment of a fee. A department for nervous diseases has been instituted in a building quite apart from the main hospital. Neurological and early mental cases are dealt with. A Course of Lectures and Practical Instruction for the Diploma in Psychological Medicine granted by the various Universities, will commence early in October. For particulars apply to the Physician Superintendent.

Hospital for Consumption and Diseases of the Chest, Brompton.—The hospital contains 333 beds. The Sanatorium at Frimley contains 100 beds and 50 beds for paying patients. Six House Physicians reside in the hospital for a term of six months; their duties include attendance in the out-patient department. Pupils are admitted to the practice of the hospital: terms £2 2*s*. for one month; three months, £4 4*s*.; six months, £7 7*s*. Clinical Demonstrations are given throughout the year by members of the medical staff. Clinical Assistants are appointed to the Assistant Physicians in the out-patient department and Clinical Clerks to the Physicians in the wards.

laboratories for Morbid Anatomy. There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in these subjects. Departments are provided and well-equipped for X ray work, both for diagnosis and treatment, the various forms of Electrical treatment, including High Frequency Currents, Electric Baths, Finsen Light treatment, and Massage.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 140 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore about 750.

Daily Post-graduate Study.—For those who are able to devote several hours each day to hospital practice the University offers special facilities for Post-graduate work. Qualified medical practitioners may be appointed as Clinical Assistants for a period of one or more months. They may act as Assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations. Fee, £3 3*s.* per month.

Post-graduate Clinical Work. — Demonstration courses with weekly lectures are held during May, June, and July. Fee, £2 2*s.* All inquiries and applications for admission should be addressed to the Director of Post-graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment at the Pathological Department.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University.

UNIVERSITY OF WALES.

This University has the privilege of granting degrees in Medicine, and Diploma in Public Health. At the four constituent colleges of Aberystwyth, Bangor, Swansea, and Cardiff, there are Professors of Chemistry, Botany, Zoology, and Physics, so that the students of the University can obtain proper instruction in the ancillary subjects. The Welsh National School of Medicine is situated in Cardiff and attached to the University College there.

University College, Cardiff. Welsh National School of Medicine.—This School is staffed on the Unit System and whole-time Professors of Medicine, Surgery, Pathology, Tuberculosis, Preventive Medicine, Physiology, and Anatomy, have already been appointed. The Courses of Instruction which are open to both men and women students are adapted to meet the needs of those preparing for Degrees in Medicine and Surgery in the University of Wales, but qualify also for Degrees in other Universities, and for the Diplomas of licensing bodies.

In the past, after having spent two or three years in study at Cardiff and having passed the corresponding examinations, students have proceeded to London and elsewhere to complete their qualifying Course for a University Degree or for a Diploma. Now, however, the Welsh National School of Medicine is fully constituted, and a complete medical curriculum will be provided at Cardiff from the beginning of next session which opens on Oct. 4th, 1921. Hospital instruction is given at the King Edward VII. Hospital, Cardiff (450 beds), and at other Institutions. The attention of students about to matriculate is drawn to the numerous entrance scholarships offered for competition at the University College, Cardiff, most of which may be held by medical students. Full particulars of the examination for these may be obtained by application to the Registrar. Instruction is given in the department of Public Health, established in 1899, in Public Health and Hygiene for those preparing for the D.P.H. examination. Courses for the training of Health Visitors and in Sanitary Science have also been instituted. Prospectus of the Welsh National School of Medicine and the School of Preventive Medicine, and Department of Public Health, can be obtained on application to the Dean of the Faculty of Medicine, or to Mr. D. J. A. Brown, Registrar, University College, Cardiff.

Clinical Instruction.—KING EDWARD VII. HOSPITAL, CARDIFF: Founded 1837. 450 beds.—SWANSEA GENERAL AND EYE HOSPITAL: Hospital, 256 beds, 186 civilians, 70 (sailor and soldier pensioners); Convalescent Home, 26 beds. The accommodation is about to be increased by 50 beds.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

Professional Examinations.—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral and partly practical. These examinations will be held in the months of January, April, July, and September or October unless otherwise appointed. Every candidate must give notice in writing to Mr. F. G. Hallett, O.B.E., Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, W.C., 14 clear days before the day of the examination, transmitting at the same time the required certificates.

The subjects of the *First Examination* are—Chemistry, Physics, and Elementary Biology. A candidate may take this examination in two parts at different times (Chemistry and Physics must be taken together until the required standard is reached in both or in one of these subjects, but a candidate will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other). A candidate will be admitted to examination in Chemistry and Physics, and in Elementary Biology on producing evidence of having passed the required Preliminary Examination and of having received instruction in these subjects at a recognised institution. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry, Physics, or Biology he must produce evidence of further instruction at a recognised institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine in any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects.

The fees for admission to the *First Examination* are as follows: For the whole examination, First Admission, £10 10*s.*; re-examination in Chemistry, Queen's Hospital for Children (*late North-Eastern Hospital for Children*), Hackney-road, Bethnal Green, E. 2. (Telephone 305 and 534 Dalston.) For the sick children of the poor under 14 years of age. Established 1867. 134 beds in London and 36 at the seaside branch, "Little Folks" Home, Bexhill.—During the past year 1713 in-patients and 56,322 out-patients (attendance 125,516) were received. The surgeons attend on Tuesdays at 1.45 p.m. and Wednesdays, Fridays and Saturdays at 9.30 a.m.; the physicians daily at 1.45 p.m., except Saturday, 9.30 a.m., and Wednesday and Friday, 9.30 a.m., as well as 1.45 p.m. The practice of the hospital is open to students by arrangement with the medical staff. Clinical demonstrations open to medical practitioners and students of medicine will be announced in the medical journals. Applications should be made to the Secretary, Mr. T. Glenton-Kerr.

Belgrave Hospital for Children, Clapham-road, S.W.—Clinical Assistants (men or women) are from time to time appointed to the members of the Visiting Staff attending in the Out-patient Department at this hospital, and facilities are given for attendance in the wards.

Alexandra Hospital for Children with Hip Disease, (late of) Queen-square, W.C.—At this hospital students who have obtained a recommendation from their teachers can attend to see the practice. In-patients, Swanley, Kent. Out-patients, St. Bartholomew's Hospital. Fridays, 1.30 p.m. Apply to the Medical Superintendent for particulars.

Royal London Ophthalmic Hospital (Moorfields, 1801–1899), City-road, E.C. 138 beds.—This hospital, known as Moorfields Eye Hospital, was moved in 1899 to larger buildings in City-road. Last year there were 2,882 in-patients, the out-patients were 50,615, of whom 43,989 were new out-patients, and the attendances were 119,219. Operations are performed daily from 10 a.m. to 1 p.m., and four surgeons attend on each day. Students are admitted to the practice of the hospital. Fee for six months, £3 3*s.*; perpetual, £5 5*s.* Special courses of instruction, which extend over a period of five months are given by members of the Surgical Staff; beginning in October and March. A composition fee of 24 guineas (£25 4*s.*) will entitle students to a perpetual ticket, and will admit them once to all the lectures and classes and to the examination for the hospital's full certificate. A special course is also held in the preliminary subjects (Anatomy, Physiology, and Optics) for the various degrees in Ophthalmology. The fee for this course is 12 guineas. Students of the hospital are eligible for the offices of house surgeon or clinical and junior assistants. Junior assistants are appointed every three months. Any further information will be furnished by Mr. Robert J. Bland, Secretary Superintendent.

Royal Westminster Ophthalmic Hospital, King William-street (next door to Charing Cross Hospital), Strand, W.C. 2.—The hospital contains 40 beds. Out-patients, who number over 13,000 annually, are seen daily at 1 p.m., and operations are performed in the theatre at 3 p.m. The practice of the hospital is open to both men and women practitioners and students. Clinical evenings, at which interesting cases are shown and discussed, are held twice each term at 8 p.m. In addition to the ordinary clinical instruction, a systematic course of Lectures and Practical Classes commences in October, January, and May. Lectures in this course are given daily (except on Saturday) at 4.30 p.m., including all subjects required by candidates for the D.O.M.S. R.C.P. & S. Eng., Part II., and practical instruction is given in Operative Surgery and Ophthalmic Pathology and Bacteriology. A course in the subjects of Part I. has been arranged at King's College, to be held each winter and summer session, covering a period of four weeks. Fees: One month, £1 1*s.*; three months, £2 2*s.*; six months, £3 3*s.*; perpetual, £5 5*s.*; composition fee for perpetual ticket and attendance at classes (except Operative Surgery and Pathology, for which fee in each case is £2 2*s.* per course), £10 10*s.* Fee for course for Part I., £10 10*s.* Students of the hospital are eligible for appointment as house surgeon, assistant house surgeon, refraction assistant, and senior or junior clinical assistant. Full details can be obtained on application to the Dean.

Royal Eye Hospital, St. George's-circus, Southwark, S.E. 1.—There are 40 beds and 2 cots. In 1920 there were 53,434 attendances in the Out-patient Department, the new patients being 22,229. Clinical instruction is given to students and post-graduates daily at 2.30 p.m., and Lectures, Demonstrations, and Laboratory Classes are arranged in preparation for examinations in Ophthalmology. Post-graduate students are eligible for appointment as Clinical Assistants and as Refraction Officers. Dean: Mr. A. D. Griffith.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—This hospital has 40 beds and clinical teaching is given daily. Classes of instruction in the use of the ophthalmoscope, with demonstrations on cases, and also classes on refraction and other subjects, to meet the requirements of the Conjoint Board for the D.O.M.S., and of the University of London for the M.S. in Ophthalmology, are given during the winter months, commencing in October. The out-patient work begins at 1 o'clock, and operations are performed daily between 2 and 4 o'clock. This school is recognised as a teaching institution by the Universities of London and Oxford, and the Conjoint Board of the Royal Colleges of Surgeons and Physicians. The school has also undertaken to receive a portion of the pupils of the University College Hospital for the purposes of ophthalmic training. The Pathological and Bacteriological Laboratories have been rendered available for the use of any ophthalmic surgeons who desire to send specimens for examination. A small fee is charged for a report. Secretary: H. R. S. Druce.

Western Ophthalmic Hospital, Marylebone-road, N.W.—16 beds. Out-patient attendances, 29,487. Both In-patient and Out-patient Departments of this Hospital are open to medical graduates. Fees £1 1*s.* per three months. Honorary Secretary: H. W. Burleigh.

National Hospital for Diseases of the Heart, Westmoreland-street, W. 1.—The practice of the Hospital is open to Post-Graduates and others. Clinical instruction is given daily in the Out-patient Department. Special Courses in Cardiology, with Lectures, Demonstrations, &c., are held periodically. Appointments as Clinical Assistants are open to Post-Graduate members of these Courses. Special instruction in Electro-Cardiography can be obtained on application to the Dean. Applications for membership of Courses or for further information should be addressed to the Secretary at the hospital.

Hospital for Diseases of the Throat, Golden-square, W. (with which is amalgamated the London Throat Hospital, Great Portland-street).—Clinical instruction in the diagnosis and treatment of disease is given daily in the out-patient department from 2 to 5 p.m., and on Tuesdays and Fridays from 6.30 to 9 p.m. The hospital contains 60 beds for in-patients. There is an annual out-patient attendance of over 60,000. Minor operations are performed Tuesdays, Wednesdays, and Thursdays, at 9.30 a.m. Major operations are performed on Tuesdays, Wednesdays, Thursdays, and Fridays, at 10 a.m. Also Thursdays and Fridays at 2 p.m. Practitioners and medical students are admitted to the practice of the hospital at a fee of £5 5*s.* for three months, £7 7*s.* for six months, or £10 10*s.* for perpetual studentship. From amongst the students junior clinical assistants are appointed periodically. For terms and further information apply to the Dean, Mr. Lionel Colledge.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—The practice of the Hospital is largely consultative. The Hospital is open daily to all qualified medical practitioners on presentation of their visiting cards. Demonstrations of the cases and clinical instruction are given daily by the chief surgeon of each clinique. Clinical Assist-qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Director of Examinations, Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

SOCIETY OF APOTHECARIES OF LONDON.

The Primary examination is held quarterly in two parts. Part I. Elementary Biology; Chemistry, Chemical Physics; Practical Chemistry; and Materia Medica and Pharmacy. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one.

The Final examination is held monthly except in September. It is in two sections. Section I. consists of three parts. Part I. Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. Medicine, Pharmacology, Pathology, and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances. Section II. of the Final examination consists of two Parts. Part I. Clinical Surgery; Part II. Clinical Medicine and Medical Anatomy.

The course of study for the *Final examination, Section I.*, includes attendance on the Surgical and Medical Practice, with Post-mortem Examinations, at a hospital connected with a medical school for a period of two winter and two summer sessions, including a course of Practical Midwifery, with attendance on 20 Midwifery cases. The course of medical study must extend over 45 months, and the offices of dresser or clinical clerk must be held at a hospital or other institution recognised by the Society. Two years must elapse after a candidate has passed the examination in Anatomy and Physiology before sitting for any part of the Final examination.

The course of study for the *Final Examination, Section II.*, includes either attendance on the Practice of Medicine and Surgery at a hospital or other institution recognised by the Society for a further period of 12 months, or six months as above and six months as a pupil of a registered practitioner holding a public medical or surgical appointment, or attendance at two special hospitals for six months (three months at each hospital), and for six months at a general hospital, all such hospitals to be recognised by the Society. Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. Candidates intending to present themselves for examination are required to give 14 days' notice. The fee for the Licence is 20 guineas. Female candidates are admitted to examinations. The examination offices are open from 10 A.M. to 4 P.M.; on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Secretary, Court of Examiners, Society of Apothecaries of London, Blackfriars, E.C. 4.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

The institutions which follow provide to the medical student and medical graduate facilities for different forms of instruction and clinical observation. In each case further information can be obtained from the secretary of the hospital.

THE SEAMEN'S HOSPITAL SOCIETY possesses three hospitals—the *Dreadnought* Hospital at Greenwich, 250 beds, and the Branch Hospital in the Royal Victoria and Albert Docks, E., 50 beds: the Hospital for Tropical Diseases, Endsleigh-gardens, 50 beds, London, N.W. 1; King George's Sanatorium for Sailors, Bramshott, Hants, and the Angas Home, 30 beds. It has also a Dispensary in the East India Dock-road from which patients are transferred to the hospitals. Secretary: Sir P. J. Michelli, C.M.G.

WEST LONDON HOSPITAL, Hammersmith, W. 6.—This hospital has 160 beds, all of which are constantly in use. 2294 in-patients and 35,466 out-patients, whose attendances numbered 195,030, were treated last year. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men, no junior students being admitted. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards every morning and afternoon. Lectures and demonstrations are given daily. Special classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Tropical Medicine, Cystoscopy, Venereal Diseases, and Operative Ophthalmology. The accommodation for post-graduates consists of a large lecture room, together with reading, writing, and class rooms, &c. The hospital has a fully equipped pathological laboratory at which instruction is given in elementary bacteriology, a class being held every month. The fees for hospital practice, including lectures, are £9 9*s.* for three months, or £23 12*s.* 6*d.* for one year. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Deans, Dr. Arthur Saunders and Mr. Bishop Harman, at the Hospital. Secretary of the Hospital: Mr. H. A. Madge.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N. 7.—This hospital is recognised by the Examining Board in England of the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the medical curriculum. Besides the Honorary Staff there are six Anæsthetists, Pathologist, Resident Medical officer, two resident House Physicians three resident House Surgeons, and resident casualty officer. The hospital contains 210 beds, which are fully occupied. There is also a ward for children under five years of age. The large rectangular and circular wards, each of which contains 25 beds, the observation wards, the two operation theatres, general and special out-patient and pathological departments, are specially designed with a view of offering the greatest facilities for clinical work. There is also a well-appointed physio-therapeutic department. The pathological department has been extended and is under the control of a Director of Clinical Pathology. The Reckitt Convalescent Home at Clacton-on-Sea belongs to the Hospital. It contains 30 beds. Special departments have also been established for the treatment of tuberculosis and venereal diseases. A Hospital of Recovery containing 60 beds has now been established at "Grovelands," Southgate, patients being removed from the main hospital by ambulance five or six days after operation. Medical practitioners are cordially invited to see the general and special practice of the hospital. Demonstrations are given daily in the wards and out-patients departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office.

Further particulars from the Secretary of the Medical Committee at the Hospital.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham. This hospital is in the midst of a densely populated neighbourhood and contains medical, surgical, gynæcological, and children's wards, having 125 beds. There are special departments for gynæcological cases, pathological laboratory. Attendance on the practice of this hospital qualifies for all the examining boards. There is also a Private Nursing Staff attached to the hospital. For particulars as to fees, &c., apply to the Matron. A new wing was added in 1897. Arrangements may be made by which gentlemen in practice desiring to increase their qualifications may have the use of the museum and library and other facilities and by which students may attend midwifery. A new Operating Theatre was opened in 1906 (the gift of Mrs. Nosworthy of Newlands, Dawlish, Devon). The Electrical Treatment Department (the gift of Mrs. M. A. Sanders) was opened in 1907 by Lady Duckworth-King. A department was opened in 1917 for the treatment of genito-urinary diseases; there are three sessions per week, two for men at 3 P.M. and 7 P.M., and one for women at 3 P.M.

West of England Eye Infirmary, Exeter.—Secretary: Mr. W. W. Beer. The infirmary contains 64 beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1920, 2985. A ward is set aside for newly-born babies suffering from infectious eye diseases. The mothers are accommodated with their babies.

Gloucestershire Royal Infirmary and Eye Institution, Gloucester.—This hospital, which was granted the title of "Royal" on the occasion of King Edward VII.'s visit to Gloucester in the year 1909, has 140 beds. Secretary: Captain G. Hurford. In-patients, 1719; out-patients, 9062. An electrical and massage department has been established and venereal clinic opened. Also ear, nose and throat department.

North Staffordshire Infirmary, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for about 250 patients, including Children's wards, and a special department for the treatment of Diseases of the Eye, a special X Ray and Electrical Department, a special department for the treatment of Diseases of the Ear, Nose, and Throat, a special orthopædic department, and venereal diseases clinics, so that there are excellent facilities for acquiring a practical knowledge of the profession. During the last six years the sum of £35,000 has been spent on new buildings and alterations. A new Out-patient Department, costing £12,000, a new Children's Ward of 30 beds, a new Pathological Department, and a second large Operation Theatre are amongst the structural improvements already completed. The whole institution is now equipped in a thoroughly up-to-date manner. Secretary and House Governor: Mr. W. Stevenson.

Hull Royal Infirmary, Hull.—This Hospital contains 256 beds, and since its establishment in 1782 until the erection of the circular wards in 1907 has undergone steady additions and improvements. A branch convalescent home and sanatorium for consumption at Withernsea are special features of the charity.

Leicester Royal Infirmary, Leicester.—Instruction in the infirmary for first-year students is duly recognised by the various examining bodies. At the General Infirmary there are 233 beds, and at the Children's Hospital in connexion 70; venereal diseases, 17; total 320. A new wing containing 100 beds is in course of construction. A reconstruction scheme has been carried out, and £200,000 spent on bringing the accommodation of the institution to a modern standard of efficiency. This scheme has included the provision of two modern operating theatres, and self-contained out-patients' department. The Children's Hospital has been reconstructed and enlarged by the addition of a third ward at a cost of £14,500. Open-air balconies on all three floors are a feature. A central sterilising department has been provided. Pathological Laboratories and post-mortem rooms have recently been opened at a cost of £11,000, also an orthopædic out-patient department at a cost of £9500, £5000 of which was provided by the Freemasons of the province as their war memorial. The Nurses' Home is at present undergoing enlargement for 60 additional bedrooms. The Royal Infirmary celebrates its 150th anniversary this year and an effort is being made to raise a sum of £100,000 in commemoration. Funds are being raised for the foundation of a City University, and a splendid site was presented by the late Mr. T. Fielding Johnson, J.P., an ex-chairman of the Royal Infirmary. There are eight resident salaried medical officers at the Infirmary—viz., four house surgeons, one house physician, one assistant house physician, and two dressers. Dressers are given an honorarium. Students are encouraged to make full use of the facilities which exist to gain clinical knowledge in the wards. The hon. medical and surgical staff are wishful of affording instruction in a variety of conditions which an active and well equipped general hospital in a large commercial centre is called upon to treat. Chairman of the Board: Mr. T. Fielding Johnson, J.P. Deputy Chairman of the Board: Mr. C. J. Bond, C.M.G., F.R.C.S. House Governor and Secretary: Mr. Harry Johnson.

Northampton General Hospital, Northampton.—Two new wings were opened in 1904 and the old buildings entirely renovated and rearranged. The number of beds is 231, 34 of which are occupied by discharged disabled pensioners. Non-resident pupils received and have every opportunity of acquiring a practical knowledge of their profession. The fee is £10 10*s.* Pupils can be received at any time. An up-to-date Pathological Laboratory has recently been erected.

Norfolk and Norwich Hospital, Norwich.—This hospital has at present 300 beds. There is a convalescent home at Cromer. Students are admitted to the practice of the Hospital for a fee of £5 5*s.* for six months. Secretary: Mr. Frank Inch.

Nottingham General Hospital.—There are at this hospital 300 beds available for medical and surgical civilian patients, 60 for pensioners, and 40 beds are in the detached ward known as "The Cedars" Convalescent Hospital. The Medical and Surgical Staffs consist of two Honorary Consulting Physicians; 3 Honorary Consulting Surgeons, 1 Honorary Consulting Physician in Venereal Diseases; 3 Honorary Physicians; 4 Honorary Surgeons; 2 Honorary Assistant Physicians; 2 Honorary Assistant Surgeons; 2 Honorary Aural Surgeons; 1 Honorary Dermatologist; 2 Honorary Anæsthetists; 1 Honorary Surgeon Dentist and 1 Honorary Medical Officer in Charge of X ray and Electro-therapeutic department. The Resident Medical Staff consists of 2 House Physicians, 4 House Surgeons and 1 Casualty Officer. The special departments are the Ear, Nose and Throat, Skin, Dental, Massage and Exercise, X ray, Orthopædic, Electro-therapeutic. House Governor and Secretary: Mr. P. M. MacColl. Assistant Secretary: Mr. John S. Birbeck.

South Devon and East Cornwall Hospital, Plymouth.—This hospital contains 188 beds (12 of which are for Venereal Diseases in a separate building). There is also an Out-patient Venereal Diseases Clinic. There is a Pathological Laboratory, Special Departments for X ray and Finsen light, an Out-patient civil Orthopædic Clinic under the Ministry of Pensions, also a civil Orthopædic Department. Pensioners are also received as in-patients. The hospital is a centre for the treatment of Tropical Diseases.

Royal Hospital, Portsmouth (founded 1847).—The number of beds is 160. The hospital has X ray and Massage Departments. The hospital is a preparatory school of Medicine and Surgery; the attendance of pupils at this hospital is recognised by the Examining Boards. Particulars of the Secretary at the hospital.

Royal Berkshire Hospital, Reading.—This hospital, which contains 220 beds, has been recently enlarged, the additions including a new Out-patient Department, a Casualty Department, an X ray Department, Electro-therapeutic and Massage Department, a V.D. clinic, a Laboratory, an Eye Theatre, and Eye Wards.

The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. Dean of the Medical School: Dr. L. S. Burrell, from whom particulars of lectures, clinical appointments, and hospital practice can be obtained.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—During the past year 1068 in-patients have been treated in the wards. The out-patients treated during 1920 numbered 12,176. Address "Secretary of the Medical Committee."

Royal Chest Hospital (for all affections of the heart and lungs), City-road, E.C. (80 beds).—This hospital provides accommodation for 80 in-patients. Expenditure for 1920 £17,103, income £15,397. The attendance of out-patients averages 35,000 annually. Secretary: Mr. A. T. Mays.

The Mount Vernon Hospital for Tuberculosis and Diseases of the Lungs and Heart, Northwood, Central Out-patient Department, Fitzroy-square, W.—The hospital contains 110 beds, Medical and Surgical. Number of in-patients, 400; out-patients, 2306. Resident Medical Staff. Clinical Demonstrations are given by the Visiting Medical Staff at the hospital at Northwood. Clinical assistants are appointed to physicians in the wards and in the out-patient department. Secretary: Mr. W. J. Morton.

Queen Charlotte's Lying-in Hospital and Midwifery Training School, Marylebone-road, N.W.—This hospital receives about 2000 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primi-parous cases—nearly one-half of the total admissions. Clinical instruction is given on the more important cases which present themselves. Special Lecture-demonstrations are given by members of the staff. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and monthly nurses are received and specially trained. A Residential College provides accommodation for five men at a time, students and qualified practitioners, and is opposite the hospital, with which it is in telephonic communication. Arrangements have been made for Medical Students to receive the preliminary instruction in Practical Midwifery recommended by the General Medical Council. Women students are received. For further particulars application should be made to Mr. Arthur Watts, Secretary, at the hospital.

Hospital for Women, Soho-square, W.—The teaching in connexion with the above hospital has been greatly extended, and is available for Post-Graduates only, in limited numbers. Every facility is afforded them, by the teaching staff, of obtaining experience in diagnosis and treatment of Gynæcological diseases. The hospital contains 68 beds, and the out-patient attendances are over 14,000 per annum. Operations take place daily at 2 o'clock except on Saturdays. The X ray department is supplied with the latest installation both for diagnosis and treatment, and experience can also be gained in the treatment of malignant disease by means of radium. Incorporated with the hospital is the London School of Gynæcology, which has three Sessions in the year, each of eight weeks duration comprising attendance in Out-patients, operating theatre, Clinical lectures, demonstrations in Pathology and X ray treatment. For further particulars apply to the Dean, Dr. Sidney Forsdike.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—Qualified practitioners are admitted as clinical assistants to both the in- and out-patient departments. Demonstrations are given daily in both departments. The fees, payable in advance, are £3 3s. for three months. Full particulars may be obtained on application to the Secretary at the hospital. There are 70 beds. Secretary: Mr. G. H. Hawkins.

East London Hospital for Children and Dispensary for Women, Glamis-road, Shadwell, E.—The hospital maintains 130 cots, and on an average 245 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, which is recognised by the Conjoint Board for England as a school of medical teaching for students in the fifth year of the curriculum. All particulars may be obtained on application to the Secretary. Two clinical clerkships for qualified or unqualified students are open every three months subject to reappointment if desired. Clinical assistants (qualified men only) are from time to time appointed in the out-patient department. Any additional information may be obtained on applying to Mr. W. M. Wilcox, the Secretary.

The Hospital for Sick Children, Great Ormond-street, W.C. 1, contains 240 beds, besides 30 beds at the Branch Hospital, Highgate. The hospital having been recognised by the Conjoint Board for England as a place where, under the new curriculum, six months of the fifth year may be spent in clinical work, the practice is arranged to meet this need and is open to students of both sexes who have completed four years of medical study and also to qualified medical men and women. The medical staff are recognised by the University of London as teachers in Diseases of Children. Arrangements have also been made with University College Hospital and the London School of Medicine for Women for the routine admission of their students of both sexes to clerkships and dresserships in the wards. Appointments are made every three months to six medical clerkships, which are open to students of the hospital. Clinical instruction is given daily by members of the visiting staff. Fees for hospital practice, one month, £2 2s.; three months, 5 guineas; perpetual ticket, 10 guineas. Clinical Clerks, 1 guinea for one month. Ophthalmological Clerkships.—Clinical Clerks are appointed once a month. Fees £1 1s. for one month's attendance. Pathological Clerkships.—Facilities are afforded for obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology in the Pathological Laboratories. Clerks attend for about four hours daily. Fees: For one month, £3 3s.; for two months, £5 5s.; for three months, £6 6s. A reduction is made in the case of those already holding tickets for general attendance at the hospital. Time so spent in clerking and dressing is recognised by the Universities of London, Oxford, and Cambridge, and by the Conjoint Board for England as part of the approved curriculum for students entering for a final examination. These appointments are open to students of all recognised medical schools. In addition, special lectures in post-graduate work are held throughout each term of the year, as well as routine post-graduate instruction daily. Details may be obtained by application to the Dean or Secretary at the hospital. The medical school is a constituent part of the new London Post-Graduate Association. Acting Sec.: Mr. James McKay.

Evelina Hospital for Sick Children, Southwark Bridge-road, S.E.—This hospital contains 70 cots and a very extensive Out-patient Department. About ten clinical assistants (either sex), to work with the Honorary Medical Staff for Out-patients, are appointed quarterly for a period of three months; there is no salary attached to these posts: but, on the other hand, no fees are charged. Secretary: H. C. Staniland Smith.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—The hospital contains 101 beds and has a large out-patient department (over 1200 weekly); the home at Broadstairs has 50 beds. Out-patients are seen as under:—Diseases of the Eye: Tuesday, 2 P.M. Diseases of the Skin: Wednesday, 1.30 P.M. Whooping-cough Cases: Friday, 2 P.M. Dental Cases: Thursday, 1.30 P.M. Medical and Surgical Cases: Mornings at 9.30 and 11.30. Accidents and urgent cases are admitted at any time. Secretary: Mr. D. St. John Bamford.

part in the Courses given under the auspices of the Edinburgh Post-Graduate Courses in Medicine. In the departments of the Faculty of Medicine, provision is made for research by students of graduate standing. In the University laboratories facilities will be provided for candidates for the Degree of Ph.D. whose applications to engage in research have been accepted by the Senatus.

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects. Full particulars can be obtained from the Dean of the Medical Faculty.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that about 1000 students avail themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards.

The practical classes and laboratories will open and the lectures commence on Oct. 5th.

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

Special courses of instruction for dental students are also included in the curriculum of this school.

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £200, payment of which is distributed over the period of study. There is no composition fee.

Further particulars regarding the school, also its calendar (price 6*d.*) may be had on application to the Dean of the School, 11, Bristo-place, Edinburgh.

Clinical Instruction.—ROYAL INFIRMARY, Edinburgh.—This hospital has 921 beds and 42 cots for children. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There are also large and complete Medico-Electrical and X Ray and Bathing Departments. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s.*; six months, £4 4*s.*; three months, £2 2*s.*; monthly, £1 1*s.* Separate payments amounting to £12 12*s.* entitle the student to a life ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows: 1. Resident physicians and surgeons are appointed and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologist.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital contains 120 beds, and is fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Full particulars can be obtained from the Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH, 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for outdoor Ear, Nose, and Throat Patients. Special Practical Ophthalmoscopic Classes by arrangement. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Secretary: Mr. J. P. Watson, W.S., 32, Charlotte-sq.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Six degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M.; B.Sc. in Public Health; D.Sc. in Public Health; and B.Sc. in Pharmacy.

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North-street, St. Andrews.

For the degrees of M.B. and Ch.B. a curriculum of five years is required. The candidate must, during his curriculum, have attended a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), two terms; with Practical Chemistry, one term; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery, two terms; Medicine, two terms. Candidates must attend for at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital. The University also requires further study in various special subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry; the second comprising Anatomy and Physiology; the third comprising Materia Medica and Therapeutics ants are appointed and are expected to hold office for at least three months. They are required to attend twice weekly at 1.30 o'clock for the afternoon, and at 4.30 o'clock for the evening Clinics. Full syllabus can be obtained on application to the Dean.

THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.—The hospital is in Fitzroy-square, W. The Out-patient Department is opened daily at 2.30 P.M. to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Tuesdays, Wednesdays, Thursdays, and Fridays at 10 A.M. Fee for one month's attendance at the hospital £3 3*s*., and for three months £5 5*s*. Clinical Assistants are appointed as vacancies occur, and have responsible duties. Applications should be made to the Honorary Secretary, Dr. Jobson Horne.

ROYAL EAR HOSPITAL.—This Hospital is now the Ear, Nose and Throat Department of University College Hospital, where all the clinics are held.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, E.C. (Founded 1835.)—The hospital contains for men and women 54 beds. Operations are performed on Mondays, Wednesdays, and Thursdays at 2.30 P.M. Medical practitioners and students are invited to the operations and to the clinical instruction in the wards and in the out-patient department. Average out-patient attendances, 4464 per year. Average in-patients, 675 per year.

ST. PETER'S HOSPITAL FOR STONE AND OTHER URINARY DISEASES, Henrietta-street, Covent Garden. Established 1860. New Hospital opened 1882.—The hospital contains 30 beds for men and 2 beds for women and children. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient department daily, and to the operations in the theatre on Mondays, Wednesdays and Fridays at 2 P.M. Average beds occupied daily, 30; average out-patients seen daily, 100.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C. 2.—The in-patient department, 40 beds, is at 262, Uxbridge-road, W. 12. The out-patient practice is open to the medical profession every day at 2 and every evening (except Saturday) at 6. At the afternoon clinics demonstrations on the different diseases presenting themselves are given. Venereal Diseases, under the Government scheme, are admitted at all clinics. The X ray department is open every afternoon except Saturday. The Chesterfield Lectures are given on Thursdays at 6 P.M., October to March, commencing Oct. 6th. At the end of the course the Chesterfield medal may be competed for by those who have attended three-fourths of the lectures. Special laboratory courses in Pathology and Bacteriology of the Skin may be arranged for.

LONDON LOCK HOSPITAL AND RESCUE HOME.—In the Institution at Harrow-road, W. 2, there are 202 beds, and 691 patients were admitted in 1920. In the Male Hospital and Out-patient Department in Dean-street, Soho, W., there are 43 beds, which during 1920 accommodated 640 patients. 99,089 out-patients were treated. 12,000 injections of the substitutes for salvarsan were made in 1920. Male patients are seen at 91, Dean-street on Mondays and Tuesdays from 1 to 2 P.M., and from 6 to 8 P.M.; on Wednesdays from 6 to 8 P.M.; on Thursdays, 5 to 7 P.M. (female patients); on Fridays from 5 to 7 P.M. (female patients); and on Saturdays from 2 to 4 P.M. (males). Pathological Department, Mondays, Tuesdays, and Wednesdays at 6.30 P.M., Thursdays and Fridays at 5 P.M., and Saturdays at 1 o'clock. Days for intravenous injections, 91, Dean-street, W. 1, Tuesdays and Saturdays at 9 A.M. (men); women, Thursdays at 5.30 P.M. Fridays at 5.30 P.M. Female patients are seen at 283, Harrow-road, Paddington, Tuesdays, Wednesdays, and Thursdays at 2 P.M. to 3 P.M., and irrigations are given every evening from 6 to 8 P.M. The next Special Course of Lectures will be held in October. Secretary, Henry J. Eason. Head Office: 283, Harrow-road, W. 9.

ENGLISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

Under this heading we include all the hospitals which are recognised by the English Royal Colleges for a part of the required attendance on medical and surgical practice, for medical clerkships, and surgical dresserships. The list includes nearly every hospital of a general character in the country having more than 150 beds, though occasionally a large hospital is omitted because equally good opportunities are afforded to students at other institutions in its neighbourhood, while a small hospital may be included because no such facilities for study are present elsewhere. The list is arranged alphabetically as to the town where the hospital is located. Most of the larger general hospitals of the kingdom have already been noticed in connexion with the Universities.

BATH ROYAL UNITED HOSPITAL, Bath.—This hospital contains 130 beds, and possesses X ray and Bacteriological Departments, and a fine library. Secretary: Mr. J. M. Sheppard. V.D. Clinics are held on Tuesdays (for women), and on Fridays and Saturdays (for men) from 5 to 7 P.M.

BEDFORD COUNTY HOSPITAL, Bedford.—This hospital has 100 beds, with X ray and Pathological Departments, and a convalescent home at Aspley Heath, near Woburn Sands, in connexion with the institution. Secretary: Mr. Beauchamp Wadmore.

BRADFORD ROYAL INFIRMARY, Bradford.—This hospital contains 215 beds. The material passing through the surgical wards consists of major operations, chiefly abdominal, and gynæcological work, and affords excellent facilities for either students or post-graduates. There are special clinics for Orthopædic and Venereal cases. Plans for a new hospital of 382 beds have been adopted, and building operations will be commenced as soon as funds will allow.

ROYAL SUSSEX COUNTY HOSPITAL, Brighton (231 beds).—This Hospital affords ample facilities for students, possessing a large out-patient department, including Ophthalmic, Dental, Dermatological, Gynæcological, X ray, and Massage sections, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years, on payment in advance of a fee, not exceeding 20 guineas, as the Board of Management shall direct.

KENT AND CANTERBURY GENERAL HOSPITAL, Canterbury.—The hospital contains 110 beds. Pupils of the staff are admitted to the practice of the hospital. Operations four days of the week. There is an Ophthalmic Department, a Venereal Clinic, an Orthopædic Department, &c. Secretary, Mr. F. P. Carroll.

COVENTRY AND WARWICKSHIRE HOSPITAL, Coventry (established 1840).—This hospital contains 241 beds, and a new wing as well as theatre and kitchens have been added. Special clinics are held for diseases of the Eyes, Ears, Nose and Throat; Gynæcology; X ray and Electrical Treatment. There are also V.D. Clinics. Clinical students are received, and there are paying wards. Secretary: Miss R. Hooper.

DERBYSHIRE ROYAL INFIRMARY, Derby.—This hospital contains 320 beds. It was founded in 1810, and was entirely rebuilt and enlarged 1892–1915 on the most modern lines at a cost of over £111,000. There is a separate ophthalmic block of 33 beds, a separate children's block of 31 beds, and a special department for gynæcological cases. There are three resident house surgeons, a resident house physician, and an assistant house surgeon and casualty officer. There are also well-equipped orthopædic X ray, electrical, and venereal diseases departments. Registered medical students are admitted to witness the medical and surgical practice on payment of 10 guineas annually.

ROYAL DEVON AND EXETER HOSPITAL, Exeter.—The hospital contains 200 beds, extending to 250 in 1922 (including special children's ward) and has a good library, museum, post-mortem room, and

Royal Infirmary, Glasgow.—The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the infirmary. St. Mungo's College is situated in the infirmary grounds. The infirmary has. including the Ophthalmic Department, 700 beds. There are special beds and wards for diseases of women, of the throat, nose, and ear, skin, venereal diseases, burns and septic cases. The wards are open to Women Students. At the Out-door Department the attendances in 1920 numbered about 168,610. In addition to the large medical and surgical departments there are departments for special diseases—viz., diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. Five house physicians and 12 house surgeons, who board in the hospital free of charge, are appointed every six months. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. The fees for Hospital Practice, Clinical Lectures, Pathology and Bacteriology are in course of revision. Post-graduate Classes are held during September in Clinical Medicine, Clinical Surgery, Clinical Gynæcology, Diseases of the Skin, Venereal Disease in the Male, Diseases of the Throat, Nose and Ear, and in Diseases of the Eye. For information regarding fees and other particulars, application should be made to the Superintendent.

Glasgow Western Infirmary.—This hospital adjoins the University of Glasgow. Number of beds upwards of 600. Special wards are set apart for Diseases of Women, Throat, Nose, and Ear, and for Affections of the Skin. In the out-patient department there are special clinics for Diseases of Women and for Diseases of the Throat, Ear, Teeth, Skin, Venereal Disease, and Electro-therapeutics. The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Eighteen resident assistants are appointed annually, without salary, from those who have completed their course. The fee for hospital attendance is £7, and the fees for clinical instruction are £3 3*s.* for the Winter Session and £2 2*s.* for the Summer Session. A Clinical Laboratory has been opened, and students receive laboratory instruction from the lecturer on clinical methods. Secretary: J. Matheson Johnston, C.A., 87, Union-st.

A School of Massage, Medical Electricity, and Swedish Remedial Exercises has been established to qualify for the Certificate of the Chartered Society of Massage and Medical Gymnastics.

Royal Hospital for Sick Children, Yorkhill, Glasgow.—This institution, which was founded in 1882, consists of: (1) a hospital at Yorkhill containing 270 cots built on an elevated and central site close to the University and opened in July, 1914; (2) a Dispensary, or Out-patient Department, in West Graham-street, opened in October, 1888; and (3) a country branch at Drumchapel, Dumbartonshire, containing 30 cots, opened in 1903. Children treated must not be over 13 years of age and suffering from non-infectious diseases. In the hospital about 5000 children are treated annually. In the Out-patient Departments over 12,000 are treated annually, involving nearly 50,000 attendances. There are two lectureships in the University of Glasgow in connexion with the hospital, one on the Medical Diseases of Infancy and Childhood, and the other on Surgery and Orthopædics in Relation to Infancy and Childhood. These lectureships are held by the Visiting Physician, Dr. Leonard Findlay, and the Visiting Surgeon, Mr. Alex. MacLennan. The lectures are both systematic and clinical, but particularly and chiefly the latter. In addition special facilities are given for post-graduate study. Information with regard to clinical instruction, lectures, demonstrations, post-graduate study, &c., may be obtained from the Med. Superintendent.

The Glasgow Royal Maternity and Women's Hospital, Rottenrow.—The new hospital, which was opened in 1908, is in point of size the largest of its kind in Britain and has accommodation for 108 patients. A Maternity and Child Welfare Centre has been established in connexion with the hospital, consisting of a complete In-door and Out-door Ante-natal Department and an Infant Consultation Clinic. In 1920 3852 normal cases and 2919 abnormal cases were treated by the hospital in the In-door and Out-door Departments. Secretary: Mr. William Guy, 146, Buchanan-street. Full particulars as to fees and accommodation may be obtained from the House Superintendent at the hospital.

Royal Samaritan Hospital for Women, Glasgow.—This hospital, founded in 1886, is one of the largest purely gynæcological hospitals in Great Britain, possessing, as it does, over 90 beds. It offers excellent facilities for clinical instruction in the diseases peculiar to women, treating in the wards and in the out-patient department some 4000 cases per annum. The surgeons, four in number, visit the wards in the mornings. For further information application may be made at the Hospital, or to Thos. Macquaker, hon. sec., 149, St. Vincent-street, Glasgow.

Glasgow Lock Hospital, 41, Rottenrow.—The hospital contains 83 beds. During 1920 493 patients were admitted to the wards; 20,577 visits were made by out-door patients at the dispensary. Classes are held for the clinical instruction of medical students and practitioners. J. Neilson Gray, LL.B., secretary and treasurer, 65, Bath-street, Glasgow.

Glasgow Ophthalmic Institution, 126, West Regent-street (30 beds and six cots).—Clinical and systematic course of lectures for students during the winter and summer sessions. In-patients, 899, out- or dispensary patients, 13,918; daily average of attendances, 137; total attendances, 38,407. Operations on Wednesdays and Saturdays. This institution is the Ophthalmic Department of the Royal Infirmary. Clinical instruction is given during both summer and winter sessions to men and women students attending the University. During September post-graduate courses will be held in connexion with the Glasgow Royal Infirmary. Secretary and Cashier: R. Morrison Smith, C.A., 135, Buchanan-street, Glasgow.

Glasgow Eye Infirmary, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The average number of new patients for the last ten years has been 26,965 and the total number of cases in 1920 was 25,952. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. A Venereal Centre has been established, and a Branch Dispensary has been opened in Clydebank. Secretary and Acting Treasurer: Harold John Black, 88, West Regent-street, Glasgow. The medical session opens in October. A Post-graduate Class will be held.

Glasgow Hospital for Diseases of the Ear, Nose, and Throat, 27 and 28, Elmbank-crescent.—12 beds and three cots. New patients, 6008. Attendances at out-patient department 20,339. Admitted to in-door department 408. Clinical instruction is given in connexion with Dr. Connal's course on Diseases of the Ear at Anderson's College and Dr. Syme's course on Diseases of the Throat and Nose at the Western Medical School. A course of post-graduate study has been conducted by the staff of the hospital. Secretary: Mr. P. T. Young.

SALISBURY GENERAL INFIRMARY, Salisbury.—This hospital contains 145 beds. The average attendance for six months is: in-patients, 102 daily average; out-patients, 830, including ophthalmic cases 102 and X ray cases 282; attendances on 1993 casuals. Secretary: Mr. S. B. Smith. These figures are for six months only.

ROYAL SALOP INFIRMARY, Shrewsbury.—This hospital has 160 beds. In-patients, 1543; out-patients, 1394; out-patients' attendances for the year, 22,688; accidents and casualties, 2228. A site has been purchased adjoining the present Infirmary structure, and it is proposed to erect an annexe for children thereon. Secretary: Mr. Alfred Sugden.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL, Southampton.—This hospital contains 130 beds. In-patients, 2255; out-patients, 9845. Secretary: Mr. T. A. Fisher Hall.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—This hospital has 102 beds. In-patients, 705; out-patients, 2623. Secretary: Lieutenant A. E. Collins.

ROYAL HANTS COUNTY HOSPITAL, Winchester.—This hospital has 180 civilian beds. Secretary: Mr. Herbert Maslen.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—There are 210 beds. Special departments for Children, Infectious cases, Gynæcology, Ear, Throat, and Nose Diseases, Electro-therapeutic and X ray, Venereal Disease, and Pathological departments. There is an excellent library. The resident officers are a resident medical officer, resident casualty surgeon and two house surgeons. Pupils are allowed to witness the whole of the practice of the hospital and to be present at operations and have every opportunity of acquiring a practical knowledge of their profession. A course of Practical Pharmacy is given by the dispenser. Fees on application. Applications should be made to the Secretary of the Medical Committee.

WORCESTER GENERAL INFIRMARY, Worcester.—This hospital has 132 beds (temporarily reduced to 70). Pupils are taken by members of the Honorary Medical and Surgical Staff. Number of operations last year 1078. New X ray and Electrical Departments have been erected and are now in use. Additional accommodation for the Honorary Staff and Out-patients and also an Outdoor Shelter in connexion with the Children's Ward have been built as a memorial to King Edward VII. In-patients, 947; out-patients, 3199. Secretary: Mr. E. J. Holland.

YORK COUNTY HOSPITAL, York.—This hospital contains 186 beds. There are balconies for outdoor treatment and two installations of X ray apparatus. A Venereal Diseases Clinic is held.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The subjects of the Qualifying examination of the Pharmaceutical Society are:—Part 1: (a) Chemistry; (b) Physics; (c) Botany. Part 2: (a) Materia Medica: (b) Pharmacy, including Posology and the Translation and Dispensing of *Prescriptions*; (c) the law relating to the keeping, selling, and dispensing of poisons and poisonous substances. Fee, 12 guineas; for each subsequent examination after failure, 3 guineas. The advanced or Major examination (for registration as "pharmaceutical chemist") includes botany, chemistry and physics, practical chemistry, and materia medica. Fee, 3 guineas. The courses of instruction given in the Society's school cover the entire ground for both examinations. Medical students are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in the School are received by the Conjoint Board of the Royal Colleges and by the University of London. Courses have been instituted in certain technical schools to prepare students for the examinations of the Pharmaceutical Society. Application for admission to the school, or for further information, may be made to the Dean, Professor Greenish, 17, Bloomsbury-square, London, W.C. 1.

II.—SCOTLAND.

THE UNIVERSITIES.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

No one is admitted to the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* who has not been engaged in Medical and Surgical study for five years.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended Clinical Surgery during a course or courses extending over not less than nine months, and courses of instruction in all the subsidiary subjects. They must have attended a course of instruction in Practical Midwifery and have personally conducted at least 12 cases of labour.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teacher as may be recognised for the purpose by the University Court. Of the subjects of study—viz., Anatomy, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than one-half must be taken in the University of Edinburgh, which corresponds to the two years above referred to.

Women are admitted to graduation in medicine under the same conditions as men.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £34 13*s*., and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First Division of the Examination (Botany, Zoology Physics, and Chemistry), £0 0*s*.; for the Second Division (Anatomy and Physiology), £7 7*s*.; for the Third Division (Pathology and Materia Medica and Therapeutics), £6 6*s*.; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery, Clinical Gynæcology, and Forensic Medicine and Public Health), £11 11*s*.

Bachelors of Medicine and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted for approval of the Faculty. The fee to be paid for the degree of M.D. is £21, and the fee to be paid for the degree of Ch.M. is £21.

Post-Graduate Instruction.—Courses of instruction are given for the Degrees of B.Sc. and D.Sc. in Public Health and for the University Diplomas in Public Health, Tropical Medicine and Hygiene, and Psychiatry. These Diplomas are open to approved registered practitioners as well as to graduates in Medicine and Surgery of the University. The University also takes they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem Examinations, Venereal Diseases, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

The fee for the degrees of M.B. and Ch.B. amounts to £23 2*s.* (Fees are to be increased from between 33⅓ per cent. to 50 per cent. commencing Session, 1921–22.)

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, and Lying-in and Vaccine Institutions, Royal Lunatic Asylum, Ophthalmic Institutions, &c.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Application for further information should be addressed to the Secretary of the Medical Faculty.

Scholarships and Prizes.—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 15 Bursaries (competition and presentation) are open each year, of £15 to £30 per annum in value, most of them being tenable for three years. Scholarships: five Post-Graduate Scholarships, value £36 to £100 per annum. Prizes and Medals: 13 Gold Medals and Prizes for proficiency in special departments, &c.

Clinical Instruction is given in the Aberdeen Royal Infirmary (270 beds) by the physicians and surgeons on the staff.

ABERDEEN ROYAL MENTAL HOSPITAL.—Contains, with hospital attached to main institution and agricultural branch, about 950 beds. Clinical instruction is given to students during three months in summer. Clerk and Treasurer, Mr. A. Scott Finnie, 343, Union-street, Aberdeen.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries.

Professional Education.—The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Physics, three months; Elementary Biology, three months; Chemistry, six months; Practical or Analytical Chemistry, three months; Anatomy, during at least six months; Practical Anatomy, twelve months; Physiology, six months; Practical Physiology, three months; Materia Medica, three months; Pathology (including Practical Pathology), nine months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery, three months; Gynæcology, one course of not less than 13 meetings; Diseases of Children, one course of not less than 13 meetings; Medical Jurisprudence and Public Health, three months. The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls. Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser. He must also attend for two and a half months instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than six months in the wards in each case, and receive practical instruction in administration of anæsthetics. He must attend for six months the practice of a public dispensary especially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital or act for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second examinations.

Candidates are also required to attend the following courses: Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months; Gynæcology, three months; Diseases of Children, three months.

The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

First Examination includes Physics, Chemistry, and Elementary Biology.

Second Examination includes Anatomy and Physiology and Histology; and candidates may be admitted to this examination at the end of the second year of medical study.

Third Examination includes Pathology and Materia Medica with Pharmacology.

Final Examination.—The Final examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women; and, if not passed previously, Medical Jurisprudence and Public Health, but it is optional to candidates who have passed the Third Examination to be admitted to the subject of Medical Jurisprudence and Public Health on lodging certificates of having attended the necessary course in that subject at any time; but the subjects of Medicine, Surgery, and Midwifery shall be taken together at any time after the end of the fifth Winter Session, provided that a period of 24 months has elapsed since passing the Second Examination. All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c. The and Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases peculiar to Women and to Infants.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

In 1919 new chairs were instituted in Bacteriology, Organic Chemistry, and Physiological Chemistry.

Fees.—The Fees for M.B. and Ch.B. are £23 2s. The class fee in each subject of the curriculum for M.B. and Ch.B. is £2 2s., £3 3s., or £4 4s., and the present fee for hospital attendance is £7. The fee for M.D. is £15 15s., and for Ch.M. £15 15s. The University Court has given notice that all class and examination fees will be increased as from Oct. 1st, 1921.

The great majority of the students take their hospital course at the Western, Royal, or Victoria Infirmary, where clinical instruction is given by professors of the University and others. Clinical instruction on Fevers is given at Ruchill and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, Dermatology, Ophthalmology, Venereal Diseases, Tuberculosis, and Insanity. Queen Margaret College, sometime conducted as a separate institution for the higher education of women, was made over to the University in 1892, and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students mostly attend the Royal Infirmary.

Post-graduate Medical Teaching.—Organised Post-graduate Medical Teaching is now available in Glasgow under the auspices of Glasgow Post-graduate Medical Association. This Association is composed of practically all the Teaching Institutions in Glasgow and the various teachers giving post-graduate instruction, and its business is managed by a Board elected periodically by them. The chairman of the Board is Principal Sir Donald MacAlister, and the vice-chairman Sir Hector C. Cameron. Weekly demonstrations for practitioners are given throughout the winter and spring, and comprehensive courses of instruction during the summer and autumn. Arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed. Further information may be obtained from Dr. A. M. Kennedy, Secretary, Post-graduate Medical Association, University, Glasgow.

In this University Bursaries and Prizes to the annual amount of over £1000 are appropriated to students in the Medical Faculty, and there are also several Scholarships and Fellowships which may be held by medical students who have gone through the Arts course. A full list will be found in the University Calendar.

THE ANDERSON COLLEGE OF MEDICINE, Dumbarton-road, Glasgow, W.—Courses are given which qualify for all the licensing boards and for the Universities of London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions). Candidates for the Licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are also conducted in the Anderson College of Medicine.

The buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, and adjoining the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health. Ample provision has also been made for the comfort of students.

Women students are admitted on the same terms as men.

The Carnegie Trust extends its benefactions to students of the Anderson College of Medicine. Full particulars may be obtained from Sir W. S. McCormick, the Carnegie Trust Offices, Merchants' Hall, Edinburgh.

Communications relating to the College to be addressed to the Secretary of the Medical Faculty, The Anderson College of Medicine, Glasgow, W. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. Hugh Cameron, M.A., F.E.I.S., Educational Institute Office, 34, North Bridge-street, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Walter Hurst, Royal Faculty Hall, 242, St. Vincent-street, Glasgow.

The Winter Session will open on Monday, Oct. 10th, 1921.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—The classes in St. Mungo's College qualify for the English, Scotch, and Irish Conjoint Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust as regards Scottish birth or extraction, age (16 years), and Preliminary Examination, are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College. The classes are open to male and female students equally. The minimum fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons, amount to £120. Further particulars can be obtained from a syllabus which may be procured free on application to the Secretary of the Medical Faculty, 86, Castle-street, Glasgow.

QUEEN MARGARET COLLEGE (*Women's Department of the University*).—This is an integral part of the University of Glasgow. The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish University, women students graduated in medicine in Glasgow University. Over 350 women have now taken the degree of M.B., C.M., or M.B., Ch.B. of the University of Glasgow and 26 the degree of M.D. The women students attend classes in the various University Buildings at Gilmore-hill, Queen Margaret College, the Royal Infirmary, and the Western Infirmary. Excellent facilities for clinical work are given in the Royal and Western Infirmaries, in the Maternity, Royal Sick Children's, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine; and by an ordinance of the Universities Commissioners women are admitted to certain University bursaries, scholarships, and fellowships. The Winter Session will open on Oct. 10th. New students of Medicine will be admitted in April, 1922. Applications for entrance at that date should be made before Feb. 1st, 1922.

Scientific Examination, including Physics and Chemistry, Botany, and Zoology. The Intermediate Medical, Part I., including Anatomy and Physiology, and Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica, Hygiene and Jurisprudence, and Pathology and Bacteriology; and Part II., Medicine, including Clinical, Surgery, Midwifery, Gynæcology, Mental Diseases, Operations, and Clinical Opthalmology. Part I. may be passed in the fourth year and Part II. completed at the end of the fifth year.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He must also read and discuss a thesis before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass a special examination.

Master in Obstetric Science.—A Master in Obstetric Science must be a Bachelor of two years' standing and produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

Diploma in Gynæcology and Obstetrics.—A post-graduate diploma is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital, a six months' course in Trinity College, and then pass a special examination.

Bachelor in Dental Science and Master in Dental Science.—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic.

All Degrees and Courses of Instruction are open to women students.

Clinical Instruction.—The hospital facilities for clinical instruction available in Dublin will be described below.

NATIONAL UNIVERSITY OF IRELAND.

Matriculation.—All students intending to proceed to the medical degree of the University of Ireland must pass a matriculation examination, the examination taking place in June and September in Dublin and at certain local centres. All students must pass in five subjects (three of which must be Irish, English, and mathematics). All students must pass in Irish except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University. The following are the subjects for examination:—1. Irish. 2. Latin or Greek. 3. French, German, Italian, Spanish, Portuguese, Welsh, or any other modern language approved by the Senate. 4. English. 5. Mathematics. 6. Latin, Greek, French, German, Welsh, Spanish, Italian, Portuguese, or any other modern language approved by the Senate, History and Geography (*as a composite subject*), Natural Philosophy, or Physics as an alternative, Chemistry, Botany, and for women candidates only, Physiology and Hygiene. Candidates who, under the regulations are exempted from the necessity of presenting Irish as one of their subjects, may present as their fifth subject either a second language or a second science subject. Students entering for degrees in Medicine or Dentistry, if already registered by the General Medical Council, may be accepted as matriculated students of the Faculty of Medicine on passing the matriculation examination in any faculty of the University.

The medical degrees granted are:—

M.B., B.Ch., and B.A.O.; and M.D., M.Ch., and M.A.O., Ph.D.—Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, Dublin."

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

UNIVERSITY COLLEGE, DUBLIN.*—The University and the College were created by the Irish University Act, 1908, and by Charters issued in December, 1908. Former students of the Cecilia-street School of Medicine who graduated in the Royal University may become graduate members of the new College. The constitution of the College, like that of the Constituent Colleges of Cork and Galway, provides for a governing body, an academic council consisting of professors and coöpted lecturers, a body of graduate members, and a body of student members matriculated in the University. The first professors and lecturers were appointed by the Dublin Commissioners Irish Universities Act, 1908.

Matriculation.—Almost all the students of the College are matriculated students of the National University of Ireland.

Universities Examinations in Medicine.—The First Examination includes Physics, Chemistry, Botany, and Zoology. The examination may be taken in two parts: Part I., Physics and Chemistry; Part II., Botany and Zoology. Honours may be obtained only when both parts are taken as one examination. The Second Examination includes Anatomy and Physiology. Both must be passed at the same time. The Third Examination includes Pathology, Medical Jurisprudence and Hygiene, and Materia Medica.

Degrees of M.B., B.Ch., and B.A.O.—The Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches. No student can enter for the M.B., B.Ch., or B.A.O. until the end of the fifth year when the curriculum has been completed. The course of study is as follows:—First year.—Winter: Anatomy and Practical Anatomy (required for the Second Examination), Chemistry, Practical Chemistry, and Experimental Physics (with Laboratory Course). Summer: Zoology, Practical Zoology, Botany, and Practical Botany. Second Year.—Winter: Anatomy, Practical Anatomy, Physiology, and Practical Physiology (physical and chemical). Summer: Anatomy, Practical Anatomy, Physiology, and Practical Histology. Third year.—Winter: Pathology, Surgery or Medicine, Hygiene, Medical Jurisprudence, and Practical Pharmacy. Summer: Materia Medica and Therapeutics, and Practical Pathology. Candidates are also required to attend a General Hospital for nine months (winter and summer). Fourth year, or fourth and fifth years.—Winter: Medicine or Surgery (the subject to be that not taken in the third year), and Midwifery and Gynæcology. Summer: Operative Surgery, Applied Anatomy, and Ophthalmology and Otology. Candidates are also required to attend a General Hospital for nine months (winter and summer), and to take instruction in Vaccination, and three months Fever Hospital. Fifth year.—If the Academic (Collegiate) Courses are taken as above, the Courses of the fifth year will be the following: Hospital Attendance, General Hospital, nine months; Clinical Ophthalmology and Otology, three months; Practical Midwifery and Gynæcology, six months; Mental Diseases, to be attended at a Lunatic Asylum, three months. (*Note.*—Practical Midwifery and Gynæcology may be taken in the fourth year after the Systematic Course of Midwifery, but it must not be taken concurrently with the period of attendance at Fever Hospital.) The degree of M.D. may be obtained either by examination or on published work.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

Four Degrees in Medicine and Surgery are conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), a Diploma in Public Health, and Diploma in Dental Surgery (L.D.S.).

The Preliminary Examination includes (*a*) English, (*b*) Latin, (*c*) Elementary Mathematics, and (*d*) one of the following optional subjects: (α) Greek, (β) French, (γ) German, (δ) Italian, (ε) any other approved modern language. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the Final Examination for the Diploma of LL.A.

Degree of Bachelor of Medicine and Bachelor of Surgery.—Candidates must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, Dermatology and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine, subject to certain provisions.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica and Pathology and Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical).

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 22 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 15 guineas, and for the degree of Master of Surgery 15 guineas. The whole medical curriculum can be taken in University College, Dundee, or the first two years in United College, St. Andrews.

For further particulars and details as to scholarships and bursaries application should be made to Prof. Charteris, Dean of the Medical Faculty, University College, Dundee.

UNIVERSITY COLLEGE, Dundee.—This College is one of the constituent colleges of the University of St. Andrews. In the medical buildings there are spacious and well-equipped laboratories. The complete medical curriculum can be taken in Dundee. For classes, fees, &c., see under University of St. Andrews.

ROYAL INFIRMARY, Dundee.—The Infirmary contains 408 beds, including special wards for the Diseases of Women, Children, Eye, Ear, and Throat, Skin, and for Obstetric cases. There is in addition an Extern Obstetric Department. There were during last year 16,997 out-patients and 727 home (maternity) patients. The Royal Infirmary offers facilities for practical work to students. *Appointments*: Seven qualified Resident Medical Officers (Male or Female) are appointed every six months and one Obstetric Assistant. Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological Department. There are in connexion with the clinical courses Tutorial Classes in Medicine and Surgery. Instruction is also given in Practical Pharmacy and Materia Medica. Further information can be obtained from the Medical Superintendent.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine (M.B.), and Bachelor of Surgery (Ch.B.).

Degrees of M.B. and Ch.B.—Before commencing his medical studies each student must comply with the following regulations: "That (*a*) the Group Certificates of the Scottish Education Department, or (*b*) the evidence of satisfactory completion in Schools in Scotland of a curriculum of Secondary Education, as attested by the said Group Certificates or otherwise, or (*c*) the Leaving or other Certificates accepted as qualifying for admission to the Universities in the case of applicants for admission from outside Scotland, which shall be deemed to entitle applicants for admission to the Universities to enter upon a course of study qualifying for Graduation in the Faculty of Medicine, shall be the same as those which, under the Regulations for the time being in force, are deemed to entitle applicants for admission to the Universities to enter upon a course of study qualifying for graduation in the Faculty of Arts or, alternatively, in the Faculty of Science, for Degrees in Pure Science."

The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects: Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Pratical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital;

Cork District Hospital (Douglas-road; 1200 beds).—This hospital includes special buildings for fever and other infectious diseases (100 beds); for children's diseases (100 beds); and a Lock hospital, the only one in the South of Ireland (80 beds). It affords an extensive field for the study of all classes of diseases, acute and chronic, including special departments for gynæcology and diseases of the skin and nervous system. The physicians and surgeons visit the hospitals every morning at 10 o'clock. Lectures and clinical instruction are given daily in the wards by the physicians and surgeons. Further particulars may be obtained from Dr. W. E. Ashley Cummins, 17, St. Patrick's-place, honorary secretary, medical staff.

Cork Eye, Ear, and Throat Hospital (Western-road).—This hospital is open to students attending the University College and others. Certificates of attendance for three or six months can be obtained. The hospital contains 35 beds. Over 4000 cases are treated during the year. A course of Lectures on Ophthalmic Surgery is delivered during the session. For further information apply to Dr. Arthur Sandford, 13, St. Patrick's-place, Cork.

University College, Galway: School of Medicine.—The College contains a well-lighted and ventilated dissecting room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. There are 12 Entrance Scholarships, value £25 each, for which Medical Students compete with other students on the Entrance Course. In the Second, Third, and Fourth years three Scholarships in each year, value £25 each, are reserved for Medical Students. Exhibitions of £10 and £5 are awarded on results of 1st, 2nd, 3rd, and Degree Examinations in Medicine. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological Society. There are abundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students. Further information can be obtained from the Registrar of the College.

Clinical Instruction is given in the Galway Hospital and in the Galway Union and Fever Hospitals, containing on an average 200 patients.

*Galway County Hospital** (62 beds).—Founded by Act of Parliament.

Galway Union and Fever Hospitals (150 beds).—Clinical instruction is given in these hospitals to the Medical Students of University College, Galway. The regulations for Scholarships tenable in the College, and the regulations for degrees and for courses can be obtained from Messrs. O'Gorman and Co., Galway.

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.), The University also grants a Diploma in Public Health, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine by the General Council of Medical Education and Registration of the United Kingdom; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission as a matriculated student of the University shall pass such Matriculation Examination or fulfil such other test of fitness as may be prescribed by the Senate, which may prescribe the conditions under which students who have passed the Matriculation or Entrance Examination of any other University or College approved for that purpose (or who have fulfilled such other test of fitness as may be prescribed) may be exempted from passing the Matriculation Examination of the University. For information as to Scholarships and Prizes inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations known as the First, Second, Third, and Fourth Medical Examinations respectively.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for this examination at the close of the third year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the First Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otology. This examination may be taken in two parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

fees payable for the Final Examination shall be—for the whole examination, £15, for re-entry after rejection, £5, and for the subjects of Medical Jurisprudence and Public Health when taken separately, £5, with £3 for re-entry in that subject.

There are four periods of examination annually: During the ensuing period, three in Edinburgh and one in Glasgow, in 1921–22. The Registrar in Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place, and the Registrar in Glasgow, Mr. Walter Hurst, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom further particulars concerning fees can be obtained.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH: THE MEMBERSHIP AND FELLOWSHIP.

In addition to the diplomas granted by the Scottish Conjoint Board the Royal College of Physicians grants its Single Licence to candidates already possessing legal qualifications for professional practice.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship.*

Membership.—A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University, approved by the Council, and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health, obstetrics, gynæcology, diseases of children, tropical medicine, or medical jurisprudence. The fee for the Membership is £36 15*s.*, 15 guineas of which will be returned to any successful candidate who was already a Licentiate of the College at the time of qualifying for the Membership.

Fellowship.—The Fellows are selected from the ranks of the *Members.* The fee is £64 18*s.*

ROYAL COLLEGE OF SURGEONS OF EDINBURGH: THE FELLOWSHIP.

The Royal College of Surgeons of Edinburgh also admits to the examination for its Single Licence any candidates who hold a Diploma in Medicine of any British, Indian, or Foreign university or of any British College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are admitted to the Licence of the College and now to the Fellowship, and the regulations apply to practitioners of either sex.

The Royal College of Surgeons of Edinburgh grants a diploma of Fellowship after examination to the holders of the surgical degrees of diplomas of such British examining bodies, as well as of the holders of such surgical degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire as are recognised by the College.

The Fellowship.—Candidates for the examination must be 25 years of age and must have been engaged in practice for at least two years. The examination is of a practical nature, partly written and partly vivâ voce, and must include surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. The fee to be paid on entering for examination for Fellowship is £45, £10 of which is remitted to those who already hold the Licentiateship of the College. Candidates rejected at the examination obtain repayment of fee less £10 retained for examination expenses. One month's notice of intention to appear for examination must be given by the candidate to Mr. D. L. Eadie, 49, Lauriston-place, Edinburgh, clerk to the College, together with credentials signed by two Fellows of the College, one of whom must be a resident in Edinburgh, otherwise a special application, with six testimonials, must be made to the President and the Council of the College.

THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Like the preceding corporations, the Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held as separate qualifications.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology or be selected from any special branch of medicine or surgery. Fourteen days' notice must be given by the candidate of his intention to present himself to Mr. Walter Hurst, the Faculty Hall, 242, St. Vincent-street, Glasgow. The fee for the Fellowship is £30, £10 of which sum are returned to any successful candidate who already holds the Licence of the Faculty. An additional sum of £20 is required in the case of candidates resident within seven miles of Glasgow. In certain circumstances Fellows may be elected as a mark of distinction.

Licence.—The Licence of the Royal Faculty is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery. The fee is 15 guineas.

SCOTTISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

The hospitals which are recognised by the Scottish Conjoint Board, as places where professional study for their diplomas can be pursued are all those institutions which feed the medical faculties of the universities. In addition the Scottish Boards recognise all the places which are recognised by the English Conjoint Board (see p. 441) and the Irish Conjoint Board (see p. 460).

III.—IRELAND.

THE UNIVERSITIES.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC).

Matriculation.—In order to join the School of Physic students pass a matriculation examination. University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary; Extern Students, any examination recognised by the General Medical Council. The winter courses begin on Oct. 1st.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Botany, Zoology, Physics and Practical Physics, Systematic, Descriptive and Applied Anatomy, Chemistry and Practical Chemistry, Histology, Physiology and Practical Physiology, Practice of Medicine, Midwifery, Pathology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene, Surgery and Operative Surgery; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 20 personally conducted cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary

Fellowship Examinations.—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and Pathology. For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars as to fees and conditions of examination can be obtained from the Registrar of the College, Stephen's-green, West Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

Every candidate for the Conjoint Examinations of the Colleges shall produce evidence of having before entering on medical studies passed a Preliminary Examination in general education recognised by the Royal Colleges. Each candidate before receiving his diplomas must produce a registrar's certificate or other satisfactory evidence that he has attained the age of 21 years.

Preliminary Examination.—The subjects for examination are identical with those prescribed for the Preliminary Examination by the General Council of Medical Education and Registration.

Professional Examinations.—Every candidate must pass four professional Examinations—at the end of the first, second, third, and fifth years respectively of his professional studies. No candidate shall be admitted to the Final or Qualifying Examination within three months of his rejection at the Final or Qualifying Examination by any other licensing body.

First Professional Examination.—Every candidate is required, before admission to the First Professional Examination, to produce evidence—(1) of having passed in the subjects of the Preliminary Examination; and (2) of having attended a course of—(*a*) lectures on Theoretical Chemistry, six months; (*b*) Practical Chemistry, three months; (*c*) Biology, three months; and (*d*) Physics.

The subjects of the First Professional Examination are the following:—1. (*a*) Chemistry; (*b*) Physics. 2. Biology. The fee for this examination is £15 15*s*.

Second Professional Examination.—Candidates are not admissible to this examination till they have passed in the subjects of the First Professional Examination, and they must produce evidence of having attended (*a*) anatomical dissections, six months; and Lectures on (*b*) Anatomy, six months; (*c*) Physiology, six months; (*d*) Practical Physiology and Histology, three months.

The subjects of the Second Professional Examination are the following:—(1) Anatomy; and (2) Physiology and Histology. The fee for this examination is £10 10*s*.

Third Professional Examination.—Every candidate is required, before admission to the Third Professional Examination, to produce evidence of having passed the Second Professional Examination, and certificates of having attended courses of instruction in (*a*) the practice of a medico-chirurgical hospital for nine months; (*b*) Pathology—(1) Systematic, (2) Practical, three months each: (*c*) Materia Medica, Pharmacy, and Therapeutics, three months; (*d*) Forensic Medicine and Public Health, three months. The subjects for the Third Professional Examination are the following:—(1) Pathology; (2) Materia Medica, Pharmacy, and Therapeutics; (3) Public Health and Forensic Medicine. The fee for this examination is £9 9*s*. Clinical instruction in Ophthalmic and Aural Surgery, three months. The examination in Ophthalmic and Aural Surgery may be taken immediately after passing the Third Professional Examination.

Final Professional Examination.—Before admission to the Final Examination candidates must have passed the Third Professional Examination and produced evidence of having attended in Division I. the practice of a medico-chirurgical hospital for two periods of nine months each (unless such evidence has been previously produced for admission in Division II.); the practice of a recognised fever hospital or the fever wards of a recognised clinical hospital, three months; clinical instruction in Mental Diseases, one month (12 attendances); lectures on Medicine, six months at a recognised medical school; of having performed the duties of medical clinical clerk in a recognised hospital for three months; of having attended a course of instruction in post-mortem examinations and demonstrations during one session. In Division II. of having attended the practice of a medico-chirurgical hospital for two periods of nine months each (unless such evidence has been previously produced for admission to Division I.); lectures on Surgery, six months at a recognised medical school; instruction in Operative Surgery, three months at a recognised medical school; of having performed the duties of surgical dresser in a recognised hospital for three months; of having attended a course of instruction in the practical administration of general anæsthetics. In Division III. of having attended a midwifery hospital or maternity and having been present at 20 labours, six months; instruction on vaccination, six attendances to be certified by a public vaccinator; lectures on midwifery (including diseases peculiar to women and to new-born children), six months at a recognised medical school. Candidates are recommended to present themselves in all the subjects of the Final Examination at one time, but a candidate at or after the end of the fourth year may present himself in any one of the Divisions I., II., or III., provided he has completed his curriculum as far as concerns the division in which he presents himself. The examination in at least one of the divisions must be deferred till the end of the fifth year.

The subjects of the Final Examination are: (1) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (2) Surgery, Operative; and (3) Midwifery and Gynæcology, Vaccination, and Diseases of New-born children. The fee is £6 6*s*. Further particulars can be obtained from Alfred Miller, O.B.E., the Secretary of the Committee of Management, Royal College of Surgeons, Stephen's-green, Dublin.

Royal College of Surgeons in Ireland (Schools of Surgery).—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes: Carmichael Scholarship, £15; Mayne Scholarship, £8; Stoney Memorial gold medal; Operative Surgery, gold and silver medals; Barker Prize, £26 5*s*.; H. Macnaughton-Jones gold medal in Obstetrics and Gynæcology; and class prizes and medals. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green, W., Dublin.

Fees.—The fees for Courses may be obtained on application to the Registrar for the College publications.

Information concerning these, and the numerous scholarships and exhibitions of the College can be obtained from the Dean of the Faculty, Professor E. P. McLoughlin.

UNIVERSITY COLLEGE, CORK: THE SCHOOL OF MEDICINE.—The building is provided with a very large, well-ventilated dissecting room supplied with electric light, with physiological, toxicological, pathological and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are well-appointed physical, chemical, and biological laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany. The Library contains about 70,000 volumes and is open daily during term time to students. The Medical Museum occupies a large room erected at the northern end of the medical buildings. There are Students' Clubs for men and women students of the College and various athletic clubs, the last of these holding a public meeting once in each year in the Mardyke grounds.

All students who have been admitted as matriculated students are required to attend before the President and sign the Roll of Matriculated Students. Students who are candidates for degrees in the National University of Ireland must have passed the Matriculation Examination of that University or other recognised examination, and medical students must have passed a preliminary examination recognised by the General Medical Council. For information as to the conditions and courses of the Matriculation Examination application may be made to the Registrar, National University, Dublin.

Admission of Medical Students.—Students in the Faculty of Medicine who have passed the First Professional Examination of the Conjoint Examinations of the Royal College of Physicians and the Royal College of Surgeons in Ireland, or of the Royal College of Physicians and Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, or of the Royal College of Physicians, London, and Royal College of Surgeons, England, may be admitted to the rank of second-year students on making application to the Council and submitting a certificate of having passed the examination. Similarly, students who have passed the Second Professional Examination of the same Colleges may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may be admitted to the rank of fourth-year students.

Residence of Students.—There is no accommodation for the residence of students within the College, but students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, a list of which can be obtained from the Secretary. All students are required to register their addresses each session in the book kept for that purpose in the hall porter's office, and to notify immediately to the Registrar any change of address during the session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students.

Clinical Instruction.—Students may attend the South Infirmary, Cork North Charitable Infirmary, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, the Cork Maternity, the Cork Fever Hospital, the Cork District Hospital, and the Cork Ear, Eye, and Throat Hospital.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, Professor A. E. Moore.

*South Infirmary and County of Cork General Hospital** (100 beds).—Clinical instruction is given daily in the wards. Special instruction on Diseases of Women and Children will be given in the special wards for such cases. Fee for nine months, £12 12*s.*; for six months, £8 8*s.*; for three months, £4 4*s.* Two resident pupils will be appointed by competitive examination.

Cork North Charitable Infirmary and County and City of Cork General Hospital * (112 beds).—Clinical instruction is given daily in the wards by the physicians and surgeons. Special instruction is given to Junior students on two days weekly. Fee for perpetual ticket, £22 1s.; for 12 or nine months, £9 9*s.*; for six months, £5 5*s.*; and for three months, £3 3*s.* Two resident pupils are appointed quarterly by the medical staff. All resident pupils are required to be registered pupils of the hospital. There is a special department for treatment of the eye, ear, throat, and nose, under the charge of Mr. J. Bowring Horgan, and a special dental department. The Hospital contains a fully equipped Pathological Department, and a large and extensive X ray Department has recently been added.

Mercy Hospital.—This hospital contains 130 beds for medical and surgical cases. There is also a daily extern for medical and surgical cases, as well as for diseases of the eye, ear, and throat. Extern medical attendances for 1920, 6657; surgical attendances, 2929; eye, ear, nose, and throat attendances, 17,174; intern patients, 1616. Major operations, 356; minor operations, 606. Minor accidents, 5720. Total extern free attendances, 32,188. Two resident students. Honorary Secretary to the Staff: Dr. D. J. O'Connor.

Cork District Lunatic Asylum.—Psychological Medicine: A course of Clinical Lectures on Mental Disease and Allied Neuroses will be delivered in the Cork District Lunatic Asylum on Mondays and Thursdays, commencing the first Thursday in May, by the Resident Medical Superintendent. All students wishing to enter for the course are expected to attend at the Asylum at 4 P.M. on that day. All information may be had at the Asylum from the resident medical superintendent.

Victoria Hospital (Incorporated) (Cork).—There are 75 beds. Clinical instruction on *Diseases Peculiar to Children* is given. The extern department is open daily at 9.30.

County and City of Cork Lying-in Hospital (Erinville, Western-road; founded 1798).—This hospital contains 22 beds, an Extern Midwifery Department, Gynæcological Department, Extern Department for Women, and Child Welfare Centre. Fee for six months' attendance, including clinical lectures, £5 5*s.* For further particulars apply to Lucy E. Smith, M.D., secretary to staff.

Cork Maternity (Batchelor's Quay).—Three resident pupils are taken into the Maternity. Poor women are attended at their own homes and there are 8 intern beds. A Child Welfare Centre and Clinic was established in 1919. Clinical lectures are delivered during the session. There is an extern department for the treatment of women's and children's diseases. Fee for attendance at clinical lectures and certificate, £5 5*s.* Honorary secretary to staff, Dr. Henry Corby.

*Cork Fever Hospital.**—Upwards of 500 cases of various forms of fever and zymotic disease are treated yearly in this hospital. The Resident Medical Officer gives instruction in Practical Pharmacy, a certificate of which is necessary for the National University and Colleges of Physicians and Surgeons of Edinburgh.

---

* In each instance an asterisk indicates that no returns have been received up to the time of going to press.

Dressers are appointed every three months, and House Surgeons and Clinical Assistants are elected annually. Apply to Hon. Treasurer of Medical Board.

Mercer's Hospital.—This hospital, founded in 1731, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within five minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of Resident Pupil, &c. There is a large dispensary for out-patients. An electrocardiograph has just been installed. Students of the hospital are permitted to attend the gynæcological department, where they receive practical instruction. There are special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements.

Appointments.—A House Surgeon is appointed annually. There are six men and two women Resident Pupils, and Clinical Clerks and Dressers are appointed from amongst the most deserving members of the class.

Fees.—Winter, six months, £8 8*s.*; Summer, three months, £5 5*s.*; nine months, £12 12*s.*

For further particulars apply to Dr. Bethel Solomons, Hon. Sec., Medical Board, 42, Fitzwilliam-square, Dublin.

National Maternity Hospital, Holles-street, Dublin.—Established 1894. The hospital consists of an Intern and Extern Maternity, and a Dispensary for the treatment of Diseases of Women and Children. About 1035 cases are admitted and over 300 operations are performed annually. Every facility is given for the carrying out of practical work. Post-graduate and special courses are arranged for at any time. Certificates of attendance at this hospital are recognised by all the licensing bodies. Terms (three months' course) 6 guineas. Board £2 2*s.* per week. Medical men can take out Post-graduate courses by paying a fee of £3 3*s.* for the first month. If he wishes to remain a second month the fee is £2 2*s.* Clinical Lectures are given daily and Oral Lectures four times per week. During the past year over 30 Post-graduate students were admitted. The L.M. Diploma is given by special examination on arrangement with the Masters. Further particulars can be obtained from the Masters: Sir Andrew Horne, 94, Merrion-square, Dublin; Dr. Reginald J. White, 23, Merrion-square, Dublin; or from the Secretary, Holles-street, Dublin.

Richmond, Whitworth, and Hardwicke Hospitals (House of Industry Hospitals), Dublin.—These hospitals contain 330 beds—130 for Surgical cases, 80 for Medical cases, 78 for Fever and other Epidemic Diseases, and an Auxiliary Wing of 42 beds. A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services. 20 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced students but also to those who are qualified in Medicine and Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. Women students are eligible for election as residents and special apartments are reserved for their use. For prospectuses apply to Mr. Adams McConnell, F.R.C.S.I., Hon.-Secretary, 69, Fitzwilliam-square, Dublin.

Rotunda Hospital, Dublin.—This institution is the largest combined gynæcological and maternity hospital in the British Empire. Over 4000 confinements are attended annually and 500 gynæcological patients admitted. Students can take out their necessary gynæcological and midwifery practical courses. The work of the hospital is carried on continuously through the year and consists of daily clinical instruction in the maternity department and examination and operations in the gynæcological department. Qualified students are given facilities for studying and assisting in the management of all abnormal cases so far as is practical. The appointments on the staff of the hospital are given to qualified past students of the hospital who have taken the L.M. and consist of Extern Assistants for six months, one being appointed every three months. From these the Assistants to the Master are appointed. Women students can reside in the hospital on the same terms as men. The L.M. is granted by examination after a six months' course. Fees for Intern students: one month £6 6*s.*, months other than the first, £4 4*s.* For further particulars apply to the Master.

Royal City of Dublin Hospital.—Founded 1832; enlarged 1851; rebuilt 1893. 130 beds. There is a special wing for the treatment of fevers and contagious diseases founded by the late Mr. Drummond. Secretary: Mr. A. J. Walkey.

Royal Victoria Eye and Ear Hospital, Dublin.—Established 1844. Incorporated 1897. 102 beds. In-patients, 1661; out-patients, 9181. Two house surgeons for Eye and one for Ear appointed annually.

Dr. Steevens' Hospital, Dublin.*—Established 1720. 250 beds. Patients, 12,834. Secretary: Mr. R. J. Ogden.

St. Vincent's Hospital and Dispensary, Dublin.—Established 1834. 200 beds. Clinical Lectures in Medicine and Surgery are held from October to June. Special classes for Juniors from October to December. Pathological and Bacteriological Demonstrations are given every Thursday and instructions in the use of laryngoscope and Otoscope for Senior students every Saturday. Medals and Prizes: the Bellingham gold medal in Medicine and the O'Farrell gold medal in Surgery are offered for competition at the end of the summer session, as well as junior prizes. In the coming term it is hoped that there will be opened a New Extern Department and a New Pathological Laboratory. Mr. Harry Meade, hon. secretary, 9, Fitzwilliam-place.

We take this opportunity of thanking the Deans and Secretaries of the various institutions for their kind coöperation in enabling us to bring the information contained in our Student's Number up to date.

Metropolitan Asylums Board: Diploma in Public Health and Instruction in Hospital Administration.—A three months' course of lectures and demonstrations will be given at the North-Western Hospital, Hampstead, N.W. 3, by Dr. E. W. Goodall, Medical Superintendent, on Tuesdays and Thursdays at 5 p.m., beginning on Tuesday, Oct. 4th, 1921. The fee for the course is £3 3*s.* Cheques should be made payable to the Metropolitan Asylums Board; medical men desiring to attend the course are required before attending at the hospital to pay this fee to the Clerk to the Medical Asylums Board, Embankment, E.C. 4, giving their full name and address.

The Chartered Society of Massage and Medical Gymnastics.—Incorporated by Royal Charter, June 9th, 1920, and amalgamating the Incorporated Society of Trained Masseuses and the Institute of Massage and Medical Gymnastics. The Chartered Society has been formed for the purpose of affording protection to the profession of massage and to its registered members: by improving the training and status of masseuses and masseurs, by providing and supervising independent examinations, by setting up registers of persons qualified to practice, by arranging post-graduate courses, lectures, and conferences, by supplying work for members (under registry regulations), and by working in all ways for the advancement and general welfare of the profession. Registration with the Chartered Society is open to all certificate holders of the Incorporated Society and of the Institute. Test examinations will be set up for the benefit of masseuses and masseurs of experience, holding certificates other than the abovementioned, who wish to register with the Chartered Society. Forms of application for registration and all information can be obtained from the offices of the Society, 157, Great Portland-street, W. 1.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject thereof.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The Musgrave Pathological Laboratory.—In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

Clinical instruction.—The following institutions are recognised by the University as affording proper opportunities for clinical instruction: the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Union Hospitals, the Belfast Hospital for Sick Children, the Belfast Maternity, the Ulster Hospital for Women and Children, the Ulster Eye, Ear, and Throat Hospital, the Belfast Ophthalmic Hospital, the Purdysburn Fever Hospital, and the Belfast District Lunatic Asylum.

Royal Victoria Hospital (300 beds).—Women students are now admitted as resident medical pupils the same as men.

Mater Infirmorum Hospital (200 beds).—Hon. Secretary Medical Staff: Mr. J. B. Moore.

Belfast Union Infirmary and Hospital (1600 beds).—Clinical courses are given biennially, and course for D.P.H. in Hospital. Intern Venereal Clinic in Infirmary under Corporation scheme. Particulars may be obtained on application, as to classes, to Dr. McLiesh.

Belfast Hospital for Sick Children, Queen-street.—Clinical instruction is given in this hospital. During the Winter Session two Courses of Lectures are delivered on the Medical and Surgical Diseases incidental to Infancy and Childhood. Demonstrations in Ophthalmology and Pathology are given, and ample opportunities are afforded in the wards (which contain 45 beds), and in the Out-patient Department, which is largely attended, for gaining a practical and theoretical knowledge of the diseases of Infancy and Childhood. This Hospital grants Certificates in Diseases of Children, which are recognised by the various Examining Bodies. A Gold Medal is offered for competition at the close of the session. Fee for the session—two guineas. For re-attendance—one guinea.

Hon. Secretary to the Medical Staff, Dr. John McCaw.

Incorporated Belfast Maternity Hospital, Townsend-street (32 beds). New Pre-Natal Clinics are being arranged in addition to the present ward clinics.

Ulster Hospital for Children and Women (44 beds).

Benn Ulster Eye, Ear, and Throat Hospital (30 beds).

Belfast Ophthalmic Hospital, Great Victoria-street (30 beds).—Practical demonstrations by the staff and occasional clinical lectures in the subjects of Ophthalmology, Otology, and Laryngology. Clinical instruction is given daily.

Belfast Fever Hospitals.—City Fever Hospital, Purdysburn (330 beds); Union Fever Hospital (200 beds). Clinical Classes are held during the winter and summer sessions. Post-Graduate (D.P.H.) Classes are also held. Lecturer: A. Gardner Robb, M.B., D.P.H.

Belfast District Lunatic Asylum (1000 beds).

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

The Membership.—Examinations for Membership are held in February, June, and November. The fee for the examination is £21 to Licentiates of the College, or £36 15*s.* to non-Licentiates. Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, Kildare-street, Dublin.

The Fellowship.—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years. There is a fee of £35 in addition to a stamp duty of £25.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Licence in Surgery.—A candidate whose name is entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, preceded by the passing of an Examination in Arts recognised by the General Medical Council, may, at the discretion of the Council, be admitted to the Examination.

Candidates are examined in Surgery, Clinical Surgery, Operative Surgery on the subject, Surgical Appliances, and Ophthalmic Surgery.

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

NAVAL MEDICAL SERVICE.

THE life offered to officers of the Royal Naval Medical Service is one that ought to appeal to a large section of recently qualified medical men. More, we have here a career which, in our opinion, many students should set before them as an object. The reasons for this opinion, we may say, are very similar to those which might induce a young medical man to enter any of the sister Services, and there is no intention in what follows, under this or the subsequent headings, to pit one Service against the other or to recruit in one direction more than in another. The particular regulations for each Service should suffice to give each man the necessary impetus for a decision.

In the Royal Naval Medical Service the young medical officer obtains these advantages. He sees the world in congenial company and with an assured position, the pay is good, the pensions are commensurate, and the opportunities offered now for scientific work are real, while, if they are taken, promotion awaits the officer on grounds of professional merit.

Rank of Surgeon Lieutenant-Commander will be granted to surgeons at the expiration of six years from date of entry, and the point upon which stress should be laid is that special promotion can be made in cases of conspicuous professional merit, which is thus placed on a par with general service. Six years later the period of promotion to Surgeon-Commander is reached, after having passed the qualifying examination, when again special promotions can be made for conspicuous professional merit as well as for distinguished service; but promotions are limited in number, save, of course, for gallantry in action. This recognition of professional attainment should prove a very real incentive to progressive scientific work. The same principle prevails in the higher ranks. Promotions to Surgeon-Captain and later to Surgeon Rear-Admiral are made strictly by selection, but are confined to officers who prove themselves to be fitted, both professionally and as administrators, for this rank.

In this connexion we cannot do better than repeat a communication from a Surgeon Rear-Admiral to whom it fell to interview a large number of medical officers who served with the Navy in a temporary capacity during the war. These men had had experience, and could give an opinion of the life, its scopes and chances, though only from the point of view of war service. But they had experienced the most trying side of naval life, and their views would expose any objections, if such there are, against the career of a naval medical officer as not giving adequate scope for a full professional life.

The first satisfactory thing to mention is that those who thought scope was wanting were mostly young men, fresh from the schools, and undoubtedly deprived of freedom or initiative through the exigencies of war. The older men who had experience of civil practice looked at the situation more broadly, for they had standards of comparison which they could employ. They were able to comprehend better what the words "professional work" implied, and did not conceive their scope limited because in ministering to the wants of a selected community of healthy men living under strict discipline there was necessarily much routine and some monotony. They looked steadily at the facts, and found that professional work in a modern battleship includes a large variety of medical and surgical cases, both acute and chronic, while emergency operations, such as those for abdominal conditions, may frequently occur. Naval life in these circumstances may lead to opportunities for putting into practice much of what has been learned in the clinical wards of a hospital. Further, the opening for preventive medicine is large and many-sided, while appointments to the large shore establishments enable medical officers to keep their work, of all kinds, up-to-date.

New chemical explosives, as well as the extraordinary behaviour of common articles under extraordinary conditions of stowage, furnish perpetual problems and surprises for the medical officer on board ship, and bring him into intimate connexion with his charges in a way that is particularly necessary considering the conditions of life. No medical officer can expect to succeed unless he secures the confidence of those committed to his charge, and the health lectures which he is bound to deliver will be much more fruitful if they are delivered to an audience which trusts him. Moreover, the delivery of official lectures does not end this side of the medical officer's duties. He must be ready to answer questions, sometimes of real acuteness, which are put to him by the modern blue-jacket, and he will find that his lectures will often afford a starting point of work that may develop into great professional interest. Thus, without his being necessarily a psychologist, his influence will be felt by both officers and men, until the well-being of the ship may be profoundly affected by the extent of his tact and skill; for example, small matters assume undue proportion under stress of confinement, and the medical officer should be quick to detect danger signs and warn his commanding officer. Numerous changes have been introduced during the last 20 years into the naval dietary, many of which were the outcome of representations and research by naval medical officers. The work wants carrying on, for much of it has gone to show that the food problem is very complicated. Every medical officer on board ship should make himself acquainted with food values and the human powers of assimilation under varying conditions of work and climate, and here there is ample scope for research. The modern requirements of gunnery and navigation necessitate precision in their use and have made ophthalmology a valuable subject for study in the Navy. The physical training of both officers and men is based on physiological axioms which are peculiarly the field of the medical officer; this training should be the subject of a watchful eye. There is no lack of scope here for professional work without making any reference to the vast problems which have to be faced when the medical officer has to arrange his particular department to the best advantage during or after an action. It is certain that he will not be able to do this unless in times of peace he gets himself ready by study. Lastly, there is the whole field of venereal and tropical disease.

The young medical officer need not be afraid that his work will be without scientific interest if he takes the opportunities offered him.

Conditions of Service.

For the time being the regulations for entry by examination into the permanent service are in abeyance, but a short service scheme providing for transfer to the permanent service has been inaugurated. The regulations for the entry of surgeon-lieutenants under this scheme provide for the usual qualifications of registration, good character, physical fitness, and age—the age not to exceed 30 years. The conditions of service are a three years' engagement with an option of a further year, to serve when and where required under the general rules of the service as regards discipline, and to rank with, but after, surgeon-lieutenants in the permanent service, and to receive two calendar months' notice of services being no longer required—that is, after two years and ten months' service.

The pay is £1 6*s*. 6*d*. per day, or £483 12*s*. 6*d*. per year, while there is a gratuity on discharge of £8 6*s*. 8*d*. for each completed month of service. A gratuity to officers invalided for causes not within their own control is payable, while the same allowances are received as are payable to permanent officers of similar rank, and lodging and provision allowances will be made and be subjected to revision from time to time. The rates mentioned are £80 a year when employed on shore without quarters, and £80 a year

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence. There are three professional examinations, the total fees for which amount to 30 guineas. Women are eligible for the diploma.

There are four examinations—primary, intermediate, Parts I. and II., and final. They are held three times a year, in March, June and December. The primary examination comprises biology, physics, theoretical and practical chemistry (with an examination at the bench). Candidates holding a Pharmaceutical licence are exempt from this subject. Intermediate, Part I., Anatomy and Physiology. Intermediate, Part II., Pathology, Medical Jurisprudence, and Materia Medica and Pharmacy. The intermediate examination comprises anatomy of the whole body (including practical dissections), physiology, practical histology, and materia medica. The final examination comprises medicine, surgery, and midwifery.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40, Mary-street, Dublin.

HOSPITALS AFFORDING PRACTICE RECOGNISED BY THE IRISH UNIVERSITIES AND CORPORATIONS.[1]

ADELAIDE HOSPITAL, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12s.; six months, £8 8s Summer, three months, £5 5s. Two resident surgeons are elected yearly and four or more resident pupils half-yearly. At the termination of the session prizes in Clinical Medicine and Surgery and in Dermatology will be awarded.

Hudson Scholarship.—In addition to the junior prizes the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in medicine, surgery, gynæcology, and pathology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Dr. H. Bewley.

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, Dublin.—This hospital contains 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. The practice of this hospital is one of the largest in Ireland. Lectures are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. There is no extra charge for attendance at this Dispensary. There is accommodation for intern pupils who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Lady medical students can reside in the hospital. The residents' quarters are comfortable. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. *Fees: Extern pupils for full* course of six months, £8 8s.; three months, £4 4s. *Intern pupils, one month, £4 4s.; each consecutive* month, £3 3s.; six months, £18 18s. Registration fee, in advance, 10s. 6d. Students can enter for attendance at any time, but preference is given to those entering from the first day of the month. Further particulars may be had on application to the Master or the Registrar at the Hospital.

SIR PATRICK DUN'S HOSPITAL, Grand Canal-street, Dublin.—Classes both in Medicine and Surgery are held each morning from 9 o'clock from Oct. 1st till the end of June. Special classes for junior students will be held in the wards during the months of October, November, and December. A Resident Surgeon, with salary, is appointed annually. Nine Resident Pupils are appointed each half-year. Six surgical Dressers and six Clinical Clerks are appointed each month. There are facilities for women students.

Prizes and Medals.—Clinical medals and prizes amounting to about £15 each will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and in Surgery provided they show sufficient merit.

Fees.—Winter and summer session, £12 12s.; winter session (six months), £8 8s.; and summer session (three months), £5 5s. Special certificate in anæsthetics, £1 1s. The practice of this hospital is open to all students, and the certificates are recognised by Dublin University, the National University and Royal Colleges of Surgeons of England, Ireland, and Scotland.

Further information will be supplied by the Hon. Secretary to the Medical Board.

JERVIS-STREET HOSPITAL, Dublin.*—Founded 1718; rebuilt 1886. 130 beds. A new out-patient department has been completed and contains all modern requirements.

MATER MISERICORDIÆ HOSPITAL, Dublin.—This hospital, the largest in Ireland, containing 382 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction will be given by the Physicians and Surgeons at 9 A.M. daily. Ophthalmic Surgery will be taught in the Special Wards and in the Dispensary. Surgical operations will be performed daily. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents. Instruction will be given on Pathology and Bacteriology. Three House Physicians, nine House Surgeons, and 16 resident pupils will be elected annually. Dressers and Clinical Clerks will also be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes will be offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. There is a Private Hospital for the reception of Medical and Surgical cases; also a Training School and a Home for Trained Nurses in connexion with the Hospital.

Terms of attendance.—Nine months, £12 12s.; six winter months, £8 8s.; three summer months, £5 5s. Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. John O'Donnell, 3, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Medical Board, Mr. H. Barniville, 9, Merrion-square.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.—This hospital was founded in 1753 and now contains 166 beds available for clinical teaching. A building containing 40 beds for the isolated treatment of fevers is attached to the hospital. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Medical Clinical Clerks and Surgical Resident Pupils and we may say have proved a marked success, form a complete answer to such criticism, however just it was in the past. This scheme of creating Directorates permits specially selected men to rise from all ranks to Major-General on the strength of their scientific work. Hitherto, a few notable men being excepted, the rule in the R.A.M.C. has been that, whatever a man's qualifications or abilities, on attaining the rank of Lieutenant-Colonel, he must be prepared to go off into administrative work and leave his scientific duties to his juniors. If he preferred to remain working in bacteriology, in preventive medicine and hygiene, or in tropical diseases, for example, he could do so, but, except in extraordinarily fortunate circumstances for himself, he would find that his devotion to science had cost him all chances of further rise in his Service, promotion being reserved for the administrative billets. The arrangement was wasteful as well as mortifying. How could the younger men be expected to preserve their interest in their scientific studies if such was the outcome? And how could their seniors be expected to remain in touch with the scientific developments in whose working out they no longer had any personal share? This now has all been changed, largely owing to the work of Sir John Goodwin, Director-General of the Service, with the assistance of Sir William Leishman and Sir William Horrocks. The change has its expression in these Directorates. Time was found during the last year of the war to prepare a scheme of reform, and to-day all up to and including the rank of Lieutenant-Colonel can draw specialist pay and hold appointments carrying allowances. The following substitutions for Articles 360 and 361 in the Royal Warrant for Pay Appointment, Promotion, and Non-effective Pay indicate the position.

---

[1] This list of the institutions recognised by the Conjoint Board of Ireland is supplemented in the regulations of the Colleges by those hospitals mentioned as recognised institutions in Scotland and England. The recognised facilities for clinical instruction in Belfast, Cork, and Galway have been described in connexion with the Belfast and National Universities.

Additional Pay and Charge Pay for Officers of the R.A.M.C.

The alterations, made under Army Order 411, 1919, became effective as from Jan. 1st, 1920:—

(1) In Article 360, *for* " officer under the rank of lieutenant-colonel appointed by Our Army Council as specialist.... 2*s.* 6*d.* a day," the following is substituted:—

" Officer not above the rank of lieutenant-colonel, while acting as specialist in a post considered by Our Army Council to merit the grant of additional pay, according to subjects or groups of subjects as under, within a limit of 5s. a day:—

Operative Surgery, advanced; Medicine; Ophthalmology; Gynæcology and Midwifery; Dermatology, including Venereal Disease, 5*s.* daily.

Otology, Laryngology, and Rhinology; Radiology; Anæsthetics; Mental Diseases; Hygiene; Pathology; subjects other than above, at the discretion of Our Army Council, 2*s.* 6*d.* daily.

Officers granted temporary higher rank while holding appointments in the services of hygiene and pathology will not be eligible for additional pay as specialists while holding such temporary rank."

(2) The following is substituted for Article 361 (*a*):—

" (*a*) Officer in charge of a hospital.—If the number of equipped beds, as certified by the Deputy Director of Medical Services, exceeds—

50 beds ..	2*s.* 6*d.* daily.	300 beds ..	7*s.* 6*d.* daily.
150 ,, ..	5*s.* 0*d.* ,,	500 ,, ..	10s. 0*d.* ,,

Officer in charge of a medical or surgical division of a general hospital with not less than 300 beds—half the above rates."

Further, an officer, graded as a specialist, and appointed to the charge of a medical or surgical division of a general hospital may be allowed to retain his additional pay and to draw the rate of charge pay laid down for the officer in charge of a medical or surgical division of a general hospital, provided that the total of additional and charge pay so drawn does not exceed the rate of charge pay drawn by the officer in charge of the hospital. With this exception charge pay and additional pay as specialist will not be issuable concurrently. It may be here pointed out that the distinction between scientific and administrative work is largely verbal. Take the conduct of a large hospital—is it possible to separate the scientific routine which is designed to ensure progressive therapeutics from the administrative work which provides and maintains the premises and service, and selects and oversees the personnel?
